CONDITIONING AN ADDITIVE FUNCTIONAL OF A MARKOV CHAIN TO STAY NON-NEGATIVE: SURVIVAL FOR A LONG TIME

Saul D Jacka, University of Warwick
Zorana Najdanovic, University of Warwick
Jon Warren, University of Warwick

Abstract

Let \((X_t)_{t \geq 0}\) be a continuous-time irreducible Markov chain on a finite statespace \(E\), let \(v\) be a map \(v : E \to \mathbb{R} \setminus \{0\}\) and let \((\varphi_t)_{t \geq 0}\) be an additive functional defined by
\[
\varphi_t = \int_0^t v(X_s)ds.
\]
We consider the cases where the process \((\varphi_t)_{t \geq 0}\) is oscillating and where \((\varphi_t)_{t \geq 0}\) has a negative drift. In each of the cases we condition the process \((X_t, \varphi_t)_{t \geq 0}\) on the event that \((\varphi_t)_{t \geq 0}\) stays non-negative until time \(T\) and prove weak convergence of the conditioned process as \(T \to \infty\).

1 Introduction

The problem of conditioning a stochastic process to stay forever in a certain region has been extensively studied in the literature. Many authors have addressed essentially the same problem by conditioning a process with a possibly finite lifetime to live forever. An interesting case is when the event that the process remains in some region is of zero probability, or in terms of the lifetime of the process restricted to the region, when the process has a finite lifetime with probability one. In that case the process cannot be conditioned to stay in the region forever in the standard way. Instead, this conditioning can be approximated by conditioning the process to stay in the region for a large time.

There are many well-known examples of such conditionings in which weak convergence of the approximating process occurs. For instance, Knight (1969) showed that the standard Brownian motion conditioned not to cross zero for a large time converges weakly to a three-dimensional Bessel process; Iglehart (1974) considered a general random walk conditioned to stay non-negative for a large time and showed that it converges weakly; Pinsky (1985) showed that under certain conditions, a homogeneous diffusion on \(\mathbb{R}^d\) conditioned to remain in an open connected bounded region for a large time converges weakly to a homogeneous diffusion; Jacka and Roberts (1988) proved weak

\[1\text{MSC Classification: Primary 60J27, Secondary 60B10} \]
\[1\text{Keywords: Markov chain, conditional law, weak convergence}\]
convergence of an Ito diffusion conditioned to remain in an interval \((a, b)\) until a large time.

However, weak convergence of the approximations does not always occur. There are counterexamples in which a process conditioned to stay in a region for a large time does not converge at all or it does converge but to a dishonest limit. Jacka and Warren (2002) gave two examples of such processes.

This paper is concerned with another example of conditioning a process to stay in a region. We consider a finite statespace continuous time Markov chain \((X_t)_{t \geq 0}\) and its associated fluctuating additive functional \((\varphi_t)_{t \geq 0}\). The aim is to condition the Markov process \((X_t, \varphi_t)_{t \geq 0}\) on the event that the fluctuating functional stays non-negative.

There are three possible cases of the behaviour of the process \((\varphi_t)_{t \geq 0}\), in two of which, when it oscillates and when it drifts to \(-\infty\), the event that it stays non-negative is of zero probability. We are interested in performing conditioning in these two cases.

A similar question has been discussed in Bertoin and Doney (1994) for a real-valued random walk. It has been shown there that, under certain conditions, an oscillating random walk or a random walk with a negative drift, conditioned to stay non-negative for large time converges weakly to an honest limit which is an \(h\)-transform of the original random walk killed when it hits zero. This work presents the analogous result for the process \((X_t, \varphi_t)_{t \geq 0}\).

The organisation of the paper is as follows: the exact formulation of the problem and results are given in Section 2, the proof of the result in the oscillating case is given in Section 3, the proof of the result in the negative drift case is given in Section 4 and the review of the notation and results used in previous sections is given in Section 5.

2 The problem and main results

Let \((X_t)_{t \geq 0}\) be an irreducible honest Markov chain on a finite statespace \(E\). Let \(v\) be a map \(v : E \to \mathbb{R} \setminus \{0\}\) and suppose that both \(E^+ = v^{-1}(0, \infty)\) and \(E^- = v^{-1}(-\infty, 0)\) are non-empty.

Define the process \((\varphi_t)_{t \geq 0}\) by

\[
\varphi_t = \varphi + \int_0^t v(X_s) \, ds, \quad \varphi \in \mathbb{R}.
\]

Let \(E^+_0 = (E \times (0, +\infty)) \cup (E^+ \times \{0\})\) and let \(H_0 = \inf\{t > 0 : \varphi_t < 0\}\). The aim is to condition the process \((X_t, \varphi_t)_{t \geq 0}\) starting in \(E^+_0\) on the event \(\{H_0 = +\infty\}\).

There are three possible cases depending on the behaviour of the process \((\varphi_t)_{t \geq 0}\).

When the process \((\varphi_t)_{t \geq 0}\) drifts to \(+\infty\), the event \(\{H_0 = +\infty\}\) is of positive probability which implies that conditioning the process \((X_t, \varphi_t)_{t \geq 0}\) on it can be performed in the standard way. However, when the process \((\varphi_t)_{t \geq 0}\) oscillates or drifts to \(-\infty\), the event \(\{H_0 = +\infty\}\) is of zero probability and conditioning \((X_t, \varphi_t)_{t \geq 0}\) on it cannot be performed in the standard way. We concentrate on these two latter cases and define conditioning
(X_t, \varphi_t)_{t \geq 0}$ on \( \{H_0 = +\infty\} \) as the limit as \( T \to \infty \) of conditioning \((X_t, \varphi_t)_{t \geq 0}\) on \( \{H_0 > t\} \).

Let \( P_{(e,\varphi)} \) denote the law of the process \((X_t, \varphi_t)_{t \geq 0}\) starting at \((e, \varphi)\), let \( P_{(e,\varphi)}^T \), \( T > 0 \), denote the law of the process \((X_t, \varphi_t)_{t \geq 0}\), starting at \((e, \varphi) \in E_0^+\), conditioned on \( \{H_0 > T\} \), and let \( P_{(e,\varphi)}^T | \mathcal{F}_t \), \( t \geq 0 \), be the restriction of \( P_{(e,\varphi)}^T \) to \( \mathcal{F}_t \), where \( (\mathcal{F}_t)_{t \geq 0} \) is the natural filtration of \((X_t)_{t \geq 0}\). We are interested in weak convergence of \( (P_{(e,\varphi)}^T | \mathcal{F}_t)_{T \geq 0} \) as \( T \to +\infty \).

Let \( Q \) denote the conservative irreducible \( Q \)-matrix of the process \((X_t)_{t \geq 0}\) and let \( V \) be the diagonal matrix \( \text{diag}(v(e)) \). Let \( V^{-1}Q = \Gamma G \) be the unique Wiener-Hopf factorisation of the matrix \( V^{-1}Q \) (see Barlow et al. (1980)). Let \( J, J_1 \) and \( J_2 \) be the matrices

\[
J = \begin{pmatrix} 1 & 0 \\ 0 & -I \end{pmatrix}, \quad J_1 = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad J_2 = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}
\]

and let a matrix \( \Gamma_2 \) be given by \( \Gamma_2 = JJ_2 \).

Now we state our main result in the oscillating case.

**Theorem 2.1** Suppose that the process \((\varphi_t)_{t \geq 0}\) oscillates. Then, for fixed \((e, \varphi) \in E_0^+\) and \( t \geq 0 \), the measures \( (P_{(e,\varphi)}^T | \mathcal{F}_t)_{T \geq 0} \) converge weakly to a probability measure \( P_{(e,\varphi)}^r \) as \( T \to \infty \), where the measure \( P_{(e,\varphi)}^r \) is defined by

\[
P_{(e,\varphi)}^r(A) = E_{(e,\varphi)}{\left( I(A)h_{r}(X_t, \varphi_t)I\{t < H_0\} \right)}, \quad t \geq 0, \ A \in \mathcal{F}_t,
\]

for \( h_r(e, y) = e^{-yV^{-1}QJ_1\Gamma_2r(e)}, (e, y) \in E \times \mathbb{R} \), and \( V^{-1}Qr = 1 \).

Let \( \beta_0 \) be the point at which the Perron-Frobenius eigenvalue \( \alpha(\beta) \) of the matrix \((Q - \beta V)\) attains its global minimum (see Lemma 5.7). Let \( a_0 = \alpha(\beta_0) \) and \( g_0 \) be the Perron-Frobenius eigenvalue and right eigenvector, respectively, of the matrix \((Q - \beta_0 V)\) and let \( G_0 \) be the diagonal matrix \( \text{diag}(g_0(e)) \). Let \( Q^0 \) be the \( E \times E \) matrix with entries

\[
Q^0(e, e') = G_0^{-1}(Q - a_0I - \beta_0 V)G_0(e, e'), \quad e, e' \in E. \tag{1}
\]

The matrix \( Q^0 \) is a conservative irreducible \( Q \)-matrix (Lemma 5.9). Let \( (V^{-1}Q^0)\Gamma^0 = \Gamma^0G^0 \) be the unique Wiener-Hopf factorization of the matrix \( V^{-1}Q^0 \) and let \( \Gamma_2^0 = JJ^0J \).

Now we can state our main result in the negative drift case.

**Theorem 2.2** Suppose that the process \((\varphi_t)_{t \geq 0}\) drifts to \(-\infty\). For fixed \((e, \varphi), (e', \varphi') \in E_0^+\) and \( t \geq 0 \), if all non-zero eigenvalues of the matrix \( V^{-1}Q^0 \) are simple and if \( \lim_{T \to +\infty} \frac{P_{(e',\varphi')(H_0 > T-t)}P_{(e,\varphi)}(H_0 > T)}{P_{(e,\varphi)}(H_0 > T)} \) exists, then the measures \( (P_{(e,\varphi)}^T | \mathcal{F}_t)_{T \geq 0} \) converge weakly as \( T \to \infty \) to a probability measure \( P_{(e,\varphi)}^o \) which is defined by

\[
P_{(e,\varphi)}^o(A) = E_{(e,\varphi)}{\left( I(A)h_o(X_t, \varphi_t)I\{t < H_0\} \right)}, \quad t \geq 0, \ A \in \mathcal{F}_t,
\]
where the function $h_{e,y}$ is given by $h_{e,y}(e,y,t) = e^{-\alpha t} e^{-\beta_{e,y} t} G_0 e^{-y V^{-1} Q_0 J_1 \Gamma_2 r_0(e)}$, $(e,y,t) \in E \times \mathbb{R} \times [0, +\infty)$, and $V^{-1} Q_0 r_0 = 1$.

### 3 The oscillating case: Proof of Theorem 2.1

We start by looking at $\lim_{T \to +\infty} P(T)^T_{(e,\varphi)}(A)$ for $A \in F_t$. By (x) (see Appendix), the events \{H_0 > T\}, $T > 0$, are of positive probability. Thus, for $0 < t < T$ and $A \in F_t$, 

$$P(T)^T_{(e,\varphi)}(A) = P_{(e,\varphi)}(A \mid H_0 > T) = \frac{E_{(e,\varphi)} \left( I(A) P_{(X_t,\varphi_0)}(H_0 > T - t I\{H_0 > t\}) \right)}{P_{(e,\varphi)}(H_0 > T)}.$$  

First we show that $\lim_{T \to +\infty} \frac{P(T)^T_{(e,\varphi)}(H_0 > T - t)}{P_{(e,\varphi)}(H_0 > T)}$ exists by looking at the asymptotic behaviour of the function $t \mapsto P_{(e,\varphi)}(H_0 > t)$.

In the oscillating case, by (16) and (iv) (see Appendix), zero is an eigenvalue of $V^{-1} Q$ with algebraic multiplicity two and geometric multiplicity one. Therefore, there exists a vector $r$ such that $V^{-1} Q r = 1$. Since the choice of such vector is not relevant in the presented work, we shall always refer to it as if it was fixed.

Let $\mu$ be the invariant measure of the process $(X_t)_{t \geq 0}$.

**Lemma 3.1** For any $(e, \varphi) \in E^+_0$, 

$$P_{(e,\varphi)}(H_0 > t) \sim \frac{1}{\pi} \frac{1}{\sqrt{-\mu V r}} t^{-\frac{1}{2}} e^{-\varphi V^{-1} Q J_1 \Gamma_2 r(e)}, \quad t \to +\infty.$$  

**Proof:** The lemma is proved by applying Tauberian theorems to the Laplace transform $rac{1}{1 - E_{(e,\varphi)}(\alpha^{-\alpha H_0})}$ of $P_{(e,\varphi)}(H_0 > t)$. By Lemmas 5.2 and 5.3 (see Appendix), for $\alpha > 0$ and $(e, \varphi) \in E^+_0$, 

$$1 - E_{(e,\varphi)}(\alpha^{-\alpha H_0}) = e^{-\varphi V^{-1} Q} \frac{1 - G_0 J_2 1}{\alpha}(e) - \frac{e^{-\varphi V^{-1} (Q - \alpha I)}}{\alpha} - \frac{e^{-\varphi V^{-1} Q}}{\alpha} \Gamma_{\alpha} J_2 1(e).$$  

Let $\beta_{\min}(\alpha)$ be the eigenvalue of $V^{-1} (Q - \alpha I)$ with minimal positive real part and let $\gamma_{\min}(\alpha)$ be its associated eigenvector. Then, by (13), $\Pi_{\alpha} g_{\min}(\alpha) = g_{\min}(\alpha)$ and by substituting $g_{\min}(\alpha)$ from Theorem 5.1 we obtain, for sufficiently small $\alpha$

$$\frac{1 + \Pi_{\alpha}^{-1}}{\alpha} = -\frac{1}{\sqrt{-\mu V r}} \frac{1}{\alpha^{-\frac{1}{2}} (r^+ - \Pi^- r^-) + \frac{1}{\sqrt{-\mu V r}} \alpha^{-\frac{1}{2}} (\Pi_{\alpha}^- - \Pi^-) r^-} + \frac{1}{\alpha} \Xi_{\min}(\alpha) + \frac{1}{\alpha} \Pi_{\alpha}^- \Xi_{\min}(\alpha).$$  

By Theorem 5.1, $\frac{1}{\alpha} \Xi_{\min}(\alpha)$ is bounded, and by (v), $\Pi_{\alpha}^- - \Pi^- \to 0$ as $\alpha \to 0$. Thus, it follows from (4) that

$$\frac{1 + \Pi_{\alpha}^{-1}}{\alpha} \sim -\frac{1}{\sqrt{-\mu V r}} \alpha^{-\frac{1}{2}} (r^+ - \Pi^- r^-), \quad \alpha \to 0.$$  

\[5\]
Since
\[ \frac{1 - \Gamma_\alpha J_2}{\alpha} = \begin{pmatrix} 1 - \frac{\alpha}{2} & -1 \\ -1 & 0 \end{pmatrix} \quad \text{and} \quad J_1 \Gamma_2 r = \begin{pmatrix} r + \Gamma - r^- \\ 0 \end{pmatrix}, \]
it follows that
\[ e^{-\varphi V^{-1}Q} \frac{1 - \Gamma_\alpha J_2}{\alpha} \sim \frac{1}{\sqrt{-\mu V r}} \alpha^{-\frac{1}{2}} e^{-\varphi V^{-1}Q} J_1 \Gamma_2 r, \quad \alpha \to 0. \]

The function \( \alpha \mapsto e^{-\varphi V^{-1}(Q - \alpha I)} \) is analytic for all \( \alpha \) and by (v), \( \Gamma_\alpha \to \Gamma \), as \( \alpha \to 0 \). Hence, the second term on the right-hand side of (3) is bounded for small \( \alpha > 0 \). Therefore, for any \((e, \varphi) \in E \times (0, +\infty)\),
\[ \frac{1 - E(e, \varphi)(e^{-\alpha H_0})}{\alpha} \sim \frac{1}{\sqrt{-\mu V r}} \alpha^{-\frac{1}{2}} e^{-\varphi V^{-1}Q} J_1 \Gamma_2 r(e), \quad \alpha \to 0. \]

The assertion in the lemma now follows from the Tauberian theorem (see Feller (1971) part 2, XIII.5). \( \square \)

**Lemma 3.2** The vector \( e^{-\varphi V^{-1}Q} J_1 \Gamma_2 r > 0 \).

**Proof:** See Jacka et al. (2004). \( \square \)

For the proof of Theorem 2.1 we need two more lemmas.

**Lemma 3.3** (i) Let \( \{f_n, n \in \mathbb{N}\} \) and \( f \) be non-negative random variables on a probability space \((\Omega, \mathcal{F}, P)\) such that \( Ef_n = Ef = 1 \), where expectation is taken with respect to the probability measure \( P \). If \( f_n \to f \) a.s. as \( n \to +\infty \), then \( f_n \to f \) in \( L^1(\Omega, \mathcal{F}, P) \) as \( n \to +\infty \).

(ii) Let \( \{P_n, n \in \mathbb{N}\} \) and \( P \) be probability measures on a measurable space \((\Omega, \mathcal{F})\) such that, for any \( A \in \mathcal{F} \), \( P_n(A) \to P(A) \) as \( n \to +\infty \). Then the measures \( \{P_n, n \in \mathbb{N}\} \) converge weakly to \( P \) on \( \mathcal{F} \).

**Proof:** (i) Since \( \{f_n, n \in \mathbb{N}\} \) and \( f \) are non-negative and \( Ef_n = Ef = 1 \), the functions \( \{f_n(\omega), n \in \mathbb{N}\} \) and \( f(\omega), \omega \in \Omega \), are densities with respect to the measure \( P \). In addition, \( f_n \to f \) a.s. as \( n \to +\infty \) and so \( f_n \to f \) in probability as \( n \to +\infty \). Therefore, by Theorem 2.2. from Jacka, Roberts (1997), \( f_n \to f \) in \( L^1(\Omega, \mathcal{F}, P) \) as \( n \to +\infty \).

(ii) For any \( A \in \mathcal{F} \), \( P_n(A) \to P(A) \) as \( n \to +\infty \). Then, by the definition of strong convergence in Jacka et.al (1997), \( P_n \) converges strongly to \( P \) which, by Theorem 2.1. in Jacka et.al (1997), implies that \( \{P_n, n \in \mathbb{N}\} \) converge weakly to \( P \). \( \square \)

**Lemma 3.4** Let \( h_r(e, \varphi) \) be a function on \( E \times \mathbb{R} \) defined by
\[ h_r(e, \varphi) = e^{-\varphi V^{-1}Q} J_1 \Gamma_2 r(e). \]
Then the process \( \{h_r(X_t, \varphi_t)I_{\{t < H_0\}, t \geq 0}\} \) is a martingale under \( P(e, \varphi) \).
Proof: The function \( h_r \) is continuously differentiable in \( \varphi \) which by (15) implies that \( h_r \) is in the domain of the infinitesimal generator \( G \) of the process \( (X_t, \varphi_t)_{t \geq 0} \) and that \( \partial G h_r = 0 \). Thus, \( (h_r(X_t, \varphi_t))_{t \geq 0} \) is a local martingale under \( P_{(e, \varphi)} \) and therefore the process \( (h_r(X_t, \varphi_t \wedge H_0))_{t \geq 0} \) is also a local martingale under \( P_{(e, \varphi)} \) (the equality of the processes is valid because \( h_r(X_t, \varphi_t \wedge H_0) = 0 \) if the process \( (X_t, \varphi_t)_{t \geq 0} \) starts in \( E_0^+ \)). Since the process \( \{h_r(X_t, \varphi_t)I\{t < H_0\}, t \geq 0\} \) is bounded on every finite interval, it follows that it is a martingale under \( P_{(e, \varphi)} \).

Proof of Theorem 2.1: For fixed \( (e, \varphi) \in E_0^+ \) and \( T \in [0, +\infty) \) let \( h_T(e, \varphi, t) \) be a random variable defined by

\[
h_T(e, \varphi, t) = \frac{P_{(X_t, \varphi_t)}(H_0 > T - t)}{P_{(e, \varphi)}(H_0 > T)} I\{t < H_0\}.
\]

Then, by Lemmas 3.1, 3.2, 3.3 (i) and 3.4 the random variables \( h_T(e, \varphi, t) \) converge to \( h_r(e, \varphi) I\{t < H_0\} \) in \( L^1(\Omega, \mathcal{F}, P_{(e, \varphi)}) \) as \( T \to +\infty \). Therefore, by (2), for fixed \( t \geq 0 \) and \( A \in \mathcal{F}_t \),

\[
\lim_{T \to +\infty} P^{T}_{(e, \varphi)}(A) = \lim_{T \to +\infty} E_{(e, \varphi)}\left(I(A)h_T(e, \varphi, t)\right)
\]

\[
= E_{(e, \varphi)}\left(I(A) \frac{h_r(X_t, \varphi_t)}{h_r(e, \varphi)} I\{t < H_0\}\right) = P^r_{(e, \varphi)}(A),
\]

which, by Lemma 3.3 (ii), implies that the measures \( (P^T_{(e, \varphi)})_{y \geq 0} \) converge weakly to \( P^r_{(e, \varphi)}|_{\mathcal{F}_t} \) as \( T \to \infty \).

4 The negative drift case: Proof of Theorem 2.2

We start again by looking at \( \lim_{T \to +\infty} P^{T}_{(e, \varphi)}(A) \) for \( A \in \mathcal{F}_t \). As in the oscillating case, we need to find \( \lim_{T \to +\infty} \frac{P_{(e', \varphi')}(H_0 > T - t)}{P_{(e, \varphi)}(H_0 > T)} \).

Lemma 4.1 Let \( h_r \) be a function on \( E \times \mathbb{R} \times [0, +\infty) \) defined by

\[
h_r(e, \varphi, t) = e^{-\alpha_0 t} e^{-\beta \varphi} G_0 e^{-\varphi V^{-1} Q_0} J_1 \Gamma_2^0 r_0(\epsilon).
\]

Then, if \( \lim_{T \to +\infty} \frac{P_{(e, \varphi)}(H_0 > T - t)}{P_{(e, \varphi)}(H_0 > T)} \) exists, it is equal to \( \frac{h_r(e', \varphi', t)}{h_r(e, \varphi, 0)} \).

For the proof of the lemma we will need some auxiliary lemmas. Let \( V^{-1}(Q^0 - \alpha I) \Gamma_0 = \Gamma_0^0 G_0^0 \) be the unique Wiener-Hopf factorisation of the matrix \( V^{-1}(Q^0 - \alpha I) \) and for fixed \( (e, \varphi) \in E \times \mathbb{R} \), let a function \( L_{(e, \varphi)}(\alpha) \), \( \alpha \geq \alpha_0 \), be defined by

\[
L_{(e, \varphi)}(\alpha) = \frac{1 - e^{-\beta \varphi} G_0 e^{-\varphi V^{-1} (Q^0 - (\alpha - \alpha_0) I)} \Gamma_0^0 \Gamma_0^{-1} J_2^1(e)}{\alpha}.
\]
By Lemmas 5.3 and 5.10, for $\alpha > 0$,

$$L_{(e,\varphi)}(\alpha) = \frac{1 - e^{-\beta_0\varphi}G_0e^{-\varphi V^{-1}(Q_0 + \alpha I)\Gamma_0^{-1}J_21}}{\alpha} = \frac{1 - E_{(e,\varphi)}(e^{-\alpha H_0})}{\alpha} = \int_0^\infty e^{-\alpha t}P_{(e,\varphi)}(H_0 > t)\, dt.$$  

(7)

**Lemma 4.2** For any $(e, \varphi) \in E_0^+$, the function $L_{(e,\varphi)}(\alpha)$ is analytic for $\Re(\alpha) > \alpha_0$.

**Proof:** By the definition in Lemma 5.3, the matrices $\Pi_0^+$ and $\Pi_0^-$ are analytic for $\Re(\alpha) > 0$. Hence, the matrix $\Gamma_0$ is analytic for $\Re(\alpha) > 0$ and therefore, by Lemma 5.10 the matrix $\Gamma_0^{-\alpha_0}$ is analytic for $\Re(\alpha) > \alpha_0$. It follows that the numerator of $L_{(e,\varphi)}(\alpha)$ in (6) is analytic for $\Re(\alpha) > \alpha_0$ and since

$$e^{-\beta_0\varphi}G_0e^{-\varphi V^{-1}(Q_0 + \alpha I)\Gamma_0^{-1}J_21} = e^{-\varphi V^{-1}Q_0J_21} = 1,$$

the numerator of $L_{(e,\varphi)}(\alpha)$ is equal to zero for $\alpha = 0$. Therefore, $L_{(e,\varphi)}(\alpha)$ is analytic for $\Re(\alpha) > \alpha_0$. \qed

We note that the objects (e.g. vectors and matrices) with the superscript 0 are associated with the matrix $Q_0$ and are defined in the same way as their counterparts associated with the matrix $Q$.

**Lemma 4.3** Let all non-zero eigenvalues of the matrix $V^{-1}Q_0$ be simple. Then, for some non-zero constant $c$,

(i) $(\Gamma_0^{\alpha_0} - \Gamma_0^0) G_0^{-1}J_21 \sim c (\alpha - \alpha_0)^{\frac{1}{2}} J_1 \Gamma_2^{0,0} r_0, \quad \alpha \to \alpha_0$,

(ii) $L_{(e,\varphi)}(\alpha) - L_{(e,\varphi)}(\alpha_0) \sim c (\alpha - \alpha_0)^{\frac{1}{2}} e^{-\beta_0\varphi}G_0 e^{-\varphi V^{-1}Q_0J_1 \Gamma_2^{0,0}(e)}, \quad \alpha \to \alpha_0$.

**Proof:** Let $g^-$ be a non-negative vector on $E^-$. Then

$$g^- = \sum_{k=1}^m a_k g_{k,0}^-$$

for some constants $a_k$, $k = 1, \ldots, m$. By (vii), the constant $a_{\min}$ which corresponds to $g_{\min} = 1^-$ in the previous linear combination is not zero. Thus,

$$\Pi_{\alpha}^{0,-}g^- = a_{\min} \Pi_{\alpha}^{0,-}1^- + \sum_{g_k^- \neq g_{\min}} a_k \Pi_{\alpha}^{0,-} g_k^-.$$  

(8)

By (16) and Lemma 5.9, the matrices $Q_0$ and $V$ define the oscillating case. Therefore, by (5),

$$1^+ - \Pi_{\alpha}^{0,-}1^- \sim \frac{1}{\sqrt{-\mu_0 V^{\mu_0}}} \alpha \frac{1}{2} \left( r_{\alpha}^{0,+} - \Pi_{\alpha}^{0,-} r_{\alpha}^{0,-} \right), \quad \alpha \to 0.$$

(9)
We also need the behaviour of $\Pi_0^0 - g_k^0$, $k = 1, \ldots, m$, $g_k^0 \neq g_{0, n}^0$. Since by assumption all non-zero eigenvalues of the matrix $V^{-1}Q^0$ are simple, it can be shown (see Wilkinson (1965)) that there exist vectors $v_{k,n}$, $n \in \mathbb{N}$, on $E$ such that

$$
\Pi_0^0 - g_k^0 = \sum_{n=1}^{\infty} a_n (v_{k,n}^+ - \Pi_0^0 - v_{k,n}^-)
$$

(10)

From (8), (9) and (10), and because by (v) $\Pi_0^0 \to \Pi_0^0$ as $\alpha \to 0$,

$$
\Pi_0^0 g - \Pi_0^0 g \sim -\frac{a_{\text{min}}}{\sqrt{-\mu^0 V^0}} \alpha^{\frac{1}{2}} (r^{0,+} - \Pi_0^0 - r^{0,-}), \quad \alpha \to 0,
$$

which proves (i).

By the definition of $L_{e, \varphi}(\alpha)$,

$$
L_{e, \varphi}(\alpha) - L_{e, \varphi}(\alpha_0) = -\frac{(\alpha - \alpha_0)(1 - e^{-\beta_0 \varphi}G_0 e^{-\varphi V^{-1}Q^0 \Gamma_0^{-1}G_0^{-1}J_21})}{\alpha \alpha_0} - \frac{\alpha_0 e^{-\beta_0 \varphi}G_0 (e^{-\varphi V^{-1}Q^0 - (\alpha - \alpha_0)} - e^{-\varphi V^{-1}Q^0}) \Gamma_0^{-1}G_0^{-1}J_21}{\alpha \alpha_0} - \frac{e^{-\beta_0 \varphi}G_0 e^{-\varphi V^{-1}Q^0} (\Gamma_0^0 - \Gamma_0) \Gamma_0^{-1}G_0^{-1}J_21}{\alpha \alpha_0} - \frac{e^{-\beta_0 \varphi}G_0 (e^{-\varphi V^{-1}Q^0 - (\alpha - \alpha_0)} - e^{-\varphi V^{-1}Q^0}) (\Gamma_0^{-1}G_0^{-1}J_21)}{\alpha \alpha_0}.
$$

Since the vector $g_0$ is positive, the vector $(G_0^{-1}J_21)^{-}$ is positive. Thus, by (i)

$$(\Gamma_0^{-1}G_0^{-1}J_21)_{\alpha - \alpha_0} \sim c (\alpha - \alpha_0)^{\frac{1}{2}} J_1 \Gamma_0^{-1}G_0^{-1}J_21, \quad \alpha \to \alpha_0,$$

for some non-zero constant $c$. In addition, the function $\alpha \mapsto e^{-\varphi V^{-1}(Q^0 - (\alpha - \alpha_0))}$ is analytic for all $\alpha$ which implies that $e^{-\varphi V^{-1}(Q^0 - (\alpha - \alpha_0))} - e^{-\varphi V^{-1}Q^0}$ is bounded for small $|\alpha - \alpha_0|$. Therefore, (ii) is valid.

**Lemma 4.4** For fixed $(e, \varphi) \in E_0^+$, the function $L_{e, \varphi}(\alpha + \alpha_0)$, $\alpha > 0$, is the Laplace transform of $e^{-\alpha_0 t}P_{e, \varphi}(H_0 > t)$.

**Proof:** By (7) $L_{e, \varphi}(\alpha)$, $\alpha > 0$, is a Laplace transform and therefore, by Theorem 1a in Feller (1971) part 2, XIII.4, completely monotone for $\alpha \geq 0$. In addition, by Lemma 4.2, $L_{e, \varphi}(\alpha)$ is analytic for $\alpha > \alpha_0$. Since the analytic continuation of a completely monotone function is completely monotone, it follows that $L_{e, \varphi}(\alpha)$ is completely monotone for $\alpha > \alpha_0$ and therefore it is a Laplace transform of some measure on $[0, +\infty)$. By the uniqueness of the inverse of the Laplace transform it follows from (7) that $L_{e, \varphi}(\alpha + \alpha_0)$ for $\alpha > 0$ is the Laplace transform of $e^{-\alpha_0 t}P_{e, \varphi}(H_0 > t)$.

\[ \square \]
Proof of Lemma 4.1: By Lemma 4.4, $\frac{L_{(e,\varphi)}}{\alpha}(t) - \frac{L_{(e,\varphi)}}{\alpha}(0)$ is the Laplace transform of the monotone function

$$t \mapsto \int_0^t e^{-\alpha s} P_{(e,\varphi)}(H_0 > s) \, ds - L_{(e,\varphi)}(0).$$

Therefore, by the Tauberian theorem (see Feller (1971) part 2, XIII.5),

$$\int_0^t e^{-\alpha s} P_{(e,\varphi)}(H_0 > s) \, ds - L_{(e,\varphi)}(0) \sim \frac{c}{\Gamma(\frac{1}{2})} t^{-\frac{1}{2}} e^{-\beta_0 \varphi} G_0 e^{-\varphi V^{-1}Q^0} J_1 \Gamma_2 r^0(e),$$

for $t \to +\infty$. Then, for fixed $(e, \varphi), (e', \varphi') \in E_0^+$,

$$\lim_{T \to +\infty} \frac{\int_0^T e^{-\alpha s} P_{(e,\varphi)}(H_0 > s) \, ds - L_{(e,\varphi)}(0)}{\int_0^T e^{-\alpha s} P_{(e',\varphi')}(H_0 > s) \, ds - L_{(e',\varphi')}(0)} = \frac{e^{-\beta_0 \varphi_0} G_0 e^{-\varphi V^{-1}Q^0} J_1 \Gamma_2 r^0(e')}{e^{-\beta_0 \varphi} G_0 e^{-\varphi V^{-1}Q^0} J_1 \Gamma_2 r^0(e)}.$$

The statement in the lemma is now proved since, by L'Hôpital’s rule,

$$\lim_{T \to +\infty} \frac{\int_0^{T-t} e^{-\alpha s} P_{(e',\varphi')}(H_0 > s) \, ds - L_{(e',\varphi')}(0)}{\int_0^{T-t} e^{-\alpha s} P_{(e,\varphi)}(H_0 > s) \, ds - L_{(e,\varphi)}(0)} = e^{\alpha t} \lim_{T \to +\infty} \frac{P_{(e',\varphi')}(H_0 > T - t)}{P_{(e,\varphi)}(H_0 > T)},$$

if the latter limit exists.

Lemma 4.5 The process $\{h_{\alpha}(X_t, \varphi, t) I\{t < H_0\}, t \geq 0\}$ is a martingale under $P_{(e,\varphi)}$.

Proof: The function $h_{\alpha}$ is continuously differentiable in $\varphi$ which by (15) implies that it is in the domain of the infinitesimal generator $G$ of the process $(X_t, \varphi, t)_{t \geq 0}$ and that $G h_{\alpha} = 0$. The rest of the proof is analogous to the proof of Lemma 3.4.

Proof of Theorem 2.2: For fixed $(e, \varphi) \in E_0^+$ and $t, T \in [0, +\infty)$ let $h_T(e, \varphi, t)$ be a random variable defined by

$$h_T(e, \varphi, t) = \frac{P_{(X_t,\varphi)}}{P_{(e,\varphi)}}(H_0 > T - t) \cdot I\{t < H_0\}.$$

Then, by Lemmas 4.1, 3.2, 3.3 (i) and 4.5 the random variables $h_T(e, \varphi, t)$ converge to $h_{\alpha}(X_t, \varphi, t) I\{t < H_0\}$ in $L^1(\Omega, F, P_{(e,\varphi)})$ as $T \to +\infty$. Therefore, by (2), for fixed $t \geq 0$ and $A \in F_t$,

$$\lim_{T \to +\infty} P_T A = \lim_{T \to +\infty} E_{(e,\varphi)}(I(A) h_T(e, \varphi, t)) = P_{(e,\varphi)}^0 A,$$

which, by Lemma 3.3 (ii), implies that the measures $(P_T^t)_{t \geq 0}$ converge weakly to $P_{(e,\varphi)}^0$ as $T \to \infty$. 

9
5 Appendix

The purpose of this section is to introduce notation and review some and prove some other results needed for the proofs in the previous two sections.

Lemma 5.1 Let \( Q \) be an irreducible essentially non-negative matrix, \( V \) a diagonal matrix and \( \beta \in \mathbb{R} \). Then the matrix \( (Q - \beta V) \) is also an irreducible essentially non-negative matrix.

\[\text{Proof:} \quad \text{The proof follows directly from the definition of an irreducible essentially non-negative matrix (see Seneta (1981)).} \]

The following three lemmas about the Wiener-Hopf factorization of the matrices \( V^{-1}(Q - \alpha I) \), \( \alpha \geq 0 \), were proved in Barlow et al. (1980). We state them here in the notation we are going to use.

Lemma 5.2 For fixed \( \alpha > 0 \), there exists a unique pair \( (\Pi_\alpha^+, \Pi_\alpha^-) \), where \( \Pi_\alpha^+ \) is an \( E^- \times E^+ \) matrix and \( \Pi_\alpha^- \) is an \( E^+ \times E^- \) matrix, and there exist \( Q \)-matrices \( G_\alpha^+ \) and \( G_\alpha^- \) on \( E^+ \times E^+ \) and \( E^- \times E^- \), respectively, such that, if

\[ \Gamma_\alpha = \begin{pmatrix} I & \Pi_\alpha^- \\ \Pi_\alpha^+ & I \end{pmatrix} \quad \text{and} \quad G_\alpha = \begin{pmatrix} G_\alpha^+ & 0 \\ 0 & -G_\alpha^- \end{pmatrix}, \]

then \( \Gamma_\alpha \) is invertible and \( \Gamma_\alpha^{-1} V^{-1}(Q - \alpha I) \Gamma_\alpha = G_\alpha \). Moreover, \( \Pi_\alpha^+ \) and \( \Pi_\alpha^- \) are strictly substochastic.

Lemma 5.3 Let \( \alpha > 0 \) be fixed. Then

\[
E_{(e,0)}(e^{-\alpha H_0} I\{X_{H_0} = e'\}) = \Pi_\alpha^+(e, e'), \quad (e, e') \in E^- \times E^+,
\]

\[
E_{(e,0)}(e^{-\alpha H_0} I\{X_{H_0} = e'\}) = \Pi_\alpha^-(e, e'), \quad (e, e') \in E^+ \times E^-,
\]

\[
E_{(e,0)}(e^{-\alpha H_y} I\{X_{H_y} = e'\}) = e^{yG_\alpha^-}(e, e'), \quad (e, e') \in E^+ \times E^+, \quad y > 0,
\]

\[
E_{(e,0)}(e^{-\alpha H_{-y}} I\{X_{H_{-y}} = e'\}) = e^{yG_\alpha^+}(e, e'), \quad (e, e') \in E^- \times E^-, \quad y > 0.
\]

Lemma 5.4 There exists a unique pair \( (\Pi^+, \Pi^-) \), where \( \Pi^+ \) is an \( E^- \times E^+ \) matrix and \( \Pi^- \) is an \( E^+ \times E^- \) matrix, and there exist \( Q \)-matrices \( G^+ \) on \( E^+ \times E^+ \) and \( G^- \) on \( E^- \times E^- \) such that

\[ (V^{-1}Q) \Gamma = \Gamma G, \quad \text{(11)} \]

where

\[ \Gamma = \begin{pmatrix} I & \Pi^- \\ \Pi^+ & I \end{pmatrix} \quad \text{and} \quad G = \begin{pmatrix} G^+ & 0 \\ 0 & -G^- \end{pmatrix}. \]

Moreover, \( \Pi^+ \) and \( \Pi^- \) are substochastic and

\[
E_{(e,0)}(X_{H_0} = e') = \Pi^+(e, e'), \quad (e, e') \in E^- \times E^+,
\]

\[
E_{(e,0)}(X_{H_0} = e') = \Pi^-(e, e'), \quad (e, e') \in E^+ \times E^-,
\]

\[
E_{(e,0)}(X_{H_y} = e') = e^{yG^+}(e, e'), \quad (e, e') \in E^+ \times E^+, \quad y \geq 0,
\]

\[
E_{(e,0)}(X_{H_{-y}} = e') = e^{yG^-}(e, e'), \quad (e, e') \in E^- \times E^-, \quad y \geq 0.
\]
It follows (see Barlow et al. (1980)) that the matrix $V^{-1}(Q - \alpha I)$ cannot have strictly imaginary eigenvalues and there exists a basis $\mathcal{B}(\alpha)$ in the space of all vectors on $E$ such that if $g(\alpha)$ is in $\mathcal{B}(\alpha)$, then

$$(V^{-1}(Q - \alpha I) - \lambda(\alpha) I)^kg(\alpha) = 0, \quad (12)$$

for some eigenvalue $\lambda(\alpha)$ of $V^{-1}(Q - \alpha I)$ and some $k \in \mathbb{N}$. The number of vectors in the basis $\mathcal{B}(\alpha)$ associated with the same eigenvalue is equal to the algebraic multiplicity of that eigenvalue. Let $\mathcal{N}(\alpha)$ and $\mathcal{P}(\alpha)$ be the sets of vectors $g(\alpha) \in \mathcal{B}(\alpha)$ associated with eigenvalues with positive and with negative real parts, respectively. Then,

$$g(\alpha) \in \mathcal{N}(\alpha) \Rightarrow g(\alpha) = \left( \frac{g^+(\alpha)}{\Pi^+g^+(\alpha)} \right), \quad g(\alpha) \in \mathcal{P}(\alpha) \Rightarrow g(\alpha) = \left( \frac{\Pi^-g^-(\alpha)}{g^-(\alpha)} \right). \quad (13)$$

The set $\mathcal{N}(\alpha)$ (respectively $\mathcal{P}(\alpha)$) contains exactly $|E^+|$ (respectively $E^-$) vectors and the vectors $g^+(\alpha)$ (respectively $g^-(\alpha)$) for all $g(\alpha) \in \mathcal{N}(\alpha)$ (respectively $\mathcal{P}(\alpha)$) form a basis in the space of all vectors on $E^+$ (respectively $E^-$). The eigenvalues of $V^{-1}(Q - \alpha I)$ with strictly negative (respectively positive) real part coincide with the eigenvalues of $G^+$ (respectively $G^-$).

The Wiener-Hopf factorization (11) of the matrix $V^{-1}Q$ implies that

$$G^+f^+ = \alpha f^+ \quad \text{iff} \quad V^{-1}Q\left( \begin{array}{c} f^+ \\ \Pi^+f^+ \end{array} \right) = \alpha \left( \begin{array}{c} f^+ \\ \Pi^+f^+ \end{array} \right)$$

$$G^-g^- = -\beta g^- \quad \text{iff} \quad V^{-1}Q\left( \begin{array}{c} g^- \\ \Pi^-g^- \end{array} \right) = \beta \left( \begin{array}{c} g^- \\ \Pi^-g^- \end{array} \right). \quad (14)$$

Let $\alpha_j$, $j = 1, \ldots, n$, be the eigenvalues (not necessarily distinct) of the matrix $G^+$, and $-\beta_k$, $k = 1, \ldots, m$, be the eigenvalues (not necessarily distinct) of the matrix $G^-$. Since by (iii) $G^+$ and $G^-$ are irreducible $Q$-matrices, it follows that

$$\alpha_{\text{max}} \equiv \max_{1 \leq j \leq n} \text{Re}(\alpha_j) \leq 0 \quad \text{and} \quad -\beta_{\text{min}} \equiv \max_{1 \leq k \leq m} \text{Re}(\beta_k) = -\min_{1 \leq k \leq m} \text{Re}(\beta_k) \leq 0$$

are simple eigenvalues of $G^+$ and $G^-$, respectively. Hence, it follows from (14) that all eigenvalues of $V^{-1}Q$ with negative (respectively positive) real part coincide with the eigenvalues of $G^+$ (respectively $G^-$).

By Jordan normal form theory there exists a basis $\mathcal{B}$ in the space of all vectors on $E$ such that there exist exactly $n = |E^+|$ vectors $\{f_1, f_2, \ldots, f_n\}$ in $\mathcal{B}$ such that each vector $f_j$, $j = 1, \ldots, n$ is associated with an eigenvalue $\alpha_j$ of $V^{-1}Q$ for which $\text{Re}(\alpha_j) \leq 0$, and that there exist exactly $m = |E^-|$ vectors $\{g_1, g_2, \ldots, g_m\}$ in $\mathcal{B}$ such that each vector $g_k$, $k = 1, \ldots, m$, is associated with an eigenvalue $\beta_k$ of $V^{-1}Q$ with $\text{Re}(\beta_k) \geq 0$. The vectors $\{f_1^+, f_2^+, \ldots, f_n^+\}$ form a basis $\mathcal{N}^+$ in the space of all vectors on $E^+$, and the vectors $\{g_1^-, g_2^-, \ldots, g_m^-\}$ form a basis $\mathcal{P}^-$ in the space of all vectors on $E^-$. Let $f_{\text{max}}$ and $g_{\text{min}}$ be the eigenvectors of the matrix $V^{-1}Q$ associated with its eigenvalues $\alpha_{\text{max}}$ and $\beta_{\text{min}}$, respectively. Then, $f_{\text{max}}^+$ and $g_{\text{min}}^-$ are the Perron-Frobenius eigenvectors of the matrices $G^+$ and $G^-$, respectively.

From Lemmas 5.2 - 5.4 it can be proved that:
(i) The matrices \( \Pi^+ \) and \( \Pi^- \) are positive.

(ii) If at least one of the matrices \( \Pi^+ \) and \( \Pi^- \) is strictly substochastic then the matrices
\[
(I - \Pi^- \Pi^+), \quad (I - \Pi^+ \Pi^-)
\]
and \( \Gamma \) are invertible and
\[
\Gamma^{-1} = \begin{pmatrix}
(I - \Pi^- \Pi^+)^{-1} & -\Pi^- (I - \Pi^+ \Pi^-)^{-1} \\
-\Pi^+ (I - \Pi^- \Pi^+)^{-1} & (I - \Pi^+ \Pi^-)^{-1}
\end{pmatrix}.
\]

(iii) The matrices \( G^+ \) and \( G^- \) are irreducible \( Q \)-matrices.

(iv) \( G^+ \) (\( G^- \)) is conservative iff \( \Pi^+ \) (\( \Pi^- \)) is stochastic.

(v) \( \lim_{\alpha \to 0} \Gamma \alpha = \Gamma \).

(vi) The vectors \( f_{\max} \) and \( g_{\min} \) are the only positive eigenvectors of the matrix \( V^{-1}Q \).

(vii) There are no non-negative vectors on \( E^+ \) (\( E^- \)) which are linearly independent of
the vector \( f_{\max} \) (\( g_{\min} \)).

(viii) For any \( y > 0 \) and \( (e, \varphi) \in E^+_0 \cap E^-_y \), or any \( y < 0 \) and \( (e, \varphi) \in E^-_0 \cap E^+_y \),
\( P_{(e,\varphi)}(X_{H_0} = e', H_y < H_0) > 0 \) and \( 0 < P_{(e,\varphi)}(H_y < H_0) < 1 \).

(ix) For any \( (e, \varphi) \in E^+_0 \) and \( e' \in E^- \), or any \( (e, \varphi) \in E^-_0 \) and \( e' \in E^+ \), \( P_{(e,\varphi)}(X_{H_0} = e', H_0 < +\infty) > 0 \).

(x) For any \( (e, \varphi) \in E \times \mathbb{R} \) and \( T > 0 \), \( P_{(e,\varphi)}(H_0 > T) > 0 \).

Let a matrix \( F(y) \), \( y \in \mathbb{R} \), be defined by
\[
F(y) = \begin{cases}
J_1 \ e^{yG} = e^{yG} \ J_1, & y > 0 \\
J_2 \ e^{yG} = e^{yG} \ J_2, & y < 0.
\end{cases}
\]

Then

**Lemma 5.5** For any \( e, e' \in E \),
\[
P_{(e,\varphi)}(X_{H_0} = e', H_0 < +\infty) = \Gamma F(-\varphi)(e, e'), \quad \varphi \neq 0,
\]
\[
P_{(e,0)}(X_{H_0} = e', H_0 < +\infty) = (I - \Gamma_2)(e, e') = \begin{pmatrix}
0 & 0 \\
\Pi^+ & 0
\end{pmatrix}
(e, e').
\]

**Proof:** The lemma follows directly from the definition of the matrices \( \Gamma \), \( \Gamma_2 \) and \( F(\varphi) \).

□

Let \( A \) be the infinitesimal generator of the process \( (X_t, \varphi_t, t)_{t \geq 0} \) and let \( D_A \) denote its domain.

Let a function \( f(e, \varphi, t) \) on \( E \times \mathbb{R} \times [0, +\infty) \) be continuously differentiable in \( \varphi \) and \( t \). Then \( f \in D_A \) and
\[
Af = \left( Q + V \frac{\partial}{\partial \varphi} + \frac{\partial}{\partial t} \right) f, \quad (15)
\]
where
\[
Qf(e, \varphi, t) = \sum_{e' \in E} Q(e, e') f(e', \varphi, t)
\]
\[
V \frac{\partial f}{\partial e}(e, \varphi, t) = V(e, e) \frac{\partial f}{\partial e}(e, \varphi, t).
\]

The behaviour of the process \((\varphi_t)_{t \geq 0}\) is determined by the matrices \(Q\) and \(V\). More precisely,
\[
(\varphi_t)_{t \geq 0} \text{ drifts to } +\infty \iff \mu V_1 > 0 \iff G^+ \text{ is conservative, } G^- \text{ is not conservative},
\]
\[
(\varphi_t)_{t \geq 0} \text{ oscillates} \iff \mu V_1 = 0 \iff G^+ \text{ and } G^- \text{ are conservative},
\]
\[
(\varphi_t)_{t \geq 0} \text{ drifts to } -\infty \iff \mu V_1 < 0 \iff G^- \text{ is conservative, } G^+ \text{ is not conservative}.
\] (16)

Let \(f_1 = f_{\max}\) and \(g_1 = g_{\min}\) be the eigenvectors of \(V^{-1}Q\) associated with the eigenvalues \(\alpha_{\max}\) and \(\beta_{\min}\), respectively. Then, in the positive drift case, \(f_{\max} = 1 \neq g_{\min}\), and in the negative drift case, \(g_{\min} = 1 \neq f_{\max}\), and in both cases the basis \(\mathcal{B}\) in the space of all vectors on \(E\) is equal to \(\{f_j, j = 1, \ldots, n, \ g_k, k = 1, \ldots, m\}\). In the oscillating case, \(f_{\max} = g_{\min} = 1\) and the equation \(V^{-1}Qx = 1\) has a solution. If \(r\) is a solution, then, by Jordan normal form theory, \(r\) is linearly independent from the vectors \(\{f_j, j = 1, \ldots, n, \ g_k, k = 1, \ldots, m\}\) and \(\mathcal{B} = \{1, r, f_j, j = 2, \ldots, n, \ g_k, k = 2, \ldots, m\}\) is a basis in the space of all vectors on \(E\).

The following lemmas are concerned with the Perron-Frobenius eigenvalue of the matrix \(Q_{\beta}V\). For any \(\beta \in \mathbb{R}\), let \(\alpha(\beta)\) be the Perron-Frobenius eigenvalue of the matrix \((Q - \beta V)\) and let \(u_{\text{left}}(\beta)\) and \(u_{\text{right}}(\beta)\) be the associated left and right eigenvectors such that \(\|u_{\text{left}}(\beta)\| = \|u_{\text{right}}(\beta)\| = 1\) in some norm in the space \(\mathbb{R}^E\). A striking property of the eigenvalue \(\alpha(\beta)\) is that it is a convex function of \(\beta\).

**Lemma 5.6** Let \(\beta \in \mathbb{R}\) and let \(\alpha(\beta)\) be the Perron-Frobenius eigenvalue of the matrix \((Q - \beta V)\). Then, \(\alpha(\beta)\) is a convex function of \(\beta\) and therefore continuous. It attains its global minimum and has two zeros, \(\alpha_{\max} \leq 0\) and \(\beta_{\min} \geq 0\), not necessarily distinct.

**Proof:** Let \(r(A)\) denote the Perron-Frobenius eigenvalue of an essentially non-negative matrix \(A\). Since \(Q\) is essentially non-negative it follows from Cohen (1981) that for any \(x, y \in \mathbb{R}\) and any \(t, 0 < t < 1\),
\[
(1 - t)(Q - xV) + t(Q - yV) \leq (1 - t) r(Q - xV) + t r(Q - yV).
\] (17)

Hence, \(\alpha(\beta)\) is a convex function and therefore continuous.

Let \(|\beta|\) be sufficiently large, then some rows of \((Q - \beta V)\) are non-negative which implies that there does not exist a positive vector \(f\) such that \((Q - \beta V)f \leq 0\). Hence, by the Perron-Frobenius theorem, \(\alpha(\beta) > 0\) for sufficiently large \(|\beta|\).

Suppose that \(\alpha(\beta) = 0\). Then there exists a positive vector \(f\) such that \((Q - \beta V)f = 0\). Since, by (VI), there exist exactly eigenvalues of \(V^{-1}Q\), \(\alpha_{\max}\) and \(\beta_{\min}\) (not necessarily distinct), whose associated eigenvectors are positive, it follows that \(\alpha_{\max}\) and \(\beta_{\min}\) are the only zeros of \(\alpha(\beta)\).
Therefore, the function $\alpha(\beta)$ is continuous, for $|\beta|$ sufficiently large it is positive and it has either one or two zeros. All of these together imply that $\alpha(\beta)$ attains its minimum.

\[ \Box \]

**Lemma 5.7** Let $\alpha(\beta)$ be the Perron-Frobenius eigenvalue and let $u^{left}(\beta)$ and $u^{right}(\beta)$ be the unit Perron-Frobenius left and right eigenvectors of the matrix $(Q - \beta V)$. Then $\alpha(\beta)$ is a differentiable function of $\beta$ and

\[
\frac{d\alpha}{d\beta}(\beta) = -\frac{u^{left}(\beta) V u^{right}(\beta)}{u^{left}(\beta) u^{right}(\beta)}.
\]

In addition, there is a unique $\beta_0 \in (\alpha_{max}, \beta_{min})$ such that $\frac{d\alpha}{d\beta}(\beta_0) = 0$ and $\alpha(\beta_0)$ is the global minimum of the function $\alpha(\beta)$ and

\[
\frac{d\alpha}{d\beta}(\beta) \begin{cases} < 0, & \text{if } \beta < \beta_0 \\ = 0, & \text{if } \beta = \beta_0 \\ > 0, & \text{if } \beta > \beta_0, \end{cases}
\]

**Proof:** By multiplying the equality

\[
(Q - \beta V) u^{right}(\beta + h) - h V u^{right}(\beta + h) = (\alpha(\beta + h) - \alpha(\beta)) u^{right}(\beta + h) + \alpha(\beta) u^{right}(\beta + h),
\]

by $\frac{u^{left}(\beta)}{h}$ and by letting $h \to 0$, we obtain that $\alpha(\beta)$ is a differentiable function of $\beta$. By Lemma 5.6 it is also convex and attains its minimum. Hence, there exists unique $\beta_0$ such that $\alpha(\beta_0)$ is the global minimum of $\alpha(\beta)$ and that $\frac{d\alpha}{d\beta}(\beta_0) = 0$. By Lemma 5.6, $\alpha(\beta)$ has two zeros, $\alpha_{max} \leq 0$ and $\beta_{min} \geq 0$. Hence, $\beta_0 \in (\alpha_{max}, \beta_{min})$ when $\alpha_{max} \neq \beta_{min}$ and $\beta_0 = \alpha_{max} = \beta_{min}$ when $\alpha_{max} = \beta_{min}$.

It remains to show that $\alpha(\beta)$ is strictly monotone on $(-\infty, \beta_0]$ and $[\beta_0, +\infty)$. Let $\alpha$ and $u(\beta)$ be the Perron-Frobenius eigenvalue and eigenvector, respectively, of $(Q - \beta V)$. Then, $u(\beta)$ is a positive eigenvector of $V^{-1}(Q - \alpha I)$.

(i) Suppose that $\beta_0 = 0$. Then $\alpha(\beta_0) = 0$ and therefore $\alpha(\beta) \geq 0$. By (VI), for $\alpha > 0$, the only positive eigenvectors of $V^{-1}(Q - \alpha I)$ are $f_{max}(\alpha)$ and $g_{min}(\alpha)$ which are associated with the eigenvalues $\alpha_{max}(\alpha)$ and $\beta_{min}(\alpha)$, respectively. Hence, for fixed $\alpha \geq \alpha_0$, there exist only two values of $\beta$, $\alpha_{max}(\alpha)$ and $\beta_{min}(\alpha)$, such that $\alpha$ is the Perron-Frobenius eigenvalue of $(Q - \beta V)$. Since $\alpha_{max}(\alpha) \leq 0$ and $\beta_{min}(\alpha) \geq 0$, it follows that $\alpha(\beta)$ is strictly monotone on both intervals $(-\infty, 0]$ and $[0, +\infty)$.

(ii) Let now $\beta_0 \in \mathbb{R}$ and let

\[
Q_0 = Q - \beta_0 V - \alpha_0 I.
\]

The matrix $Q_0$ is essentially non-negative and, by Lemma 5.1, irreducible, and so is the matrix $(Q_0 - \beta V)$ for any $\beta \in \mathbb{R}$. Let $\alpha_0(\beta)$ be the Perron-Frobenius eigenvalue
of \((Q_0 - \beta V)\). Then \(\alpha_0(\beta) = \alpha(\beta + \beta_0) - \alpha_0\). Since \(\alpha(\beta)\) attains its global minimum at \(\beta = \beta_0\), it follows that \(\alpha_0(\beta)\) attains its global minimum zero at \(\beta = 0\). Therefore, by (i), \(\alpha_0(\beta)\) is strictly monotone on \((-\infty, 0]\) and \([0, +\infty)\), which implies that \(\alpha(\beta)\) is strictly monotone on \((-\infty, \beta_0]\) and \([\beta_0, +\infty)\).

The sign of the unique argument \(\beta_0\) of the global minimum of the function \(\alpha(\beta)\), whose existence has been proved in the previous lemma, is found to depend on the behaviour of the process \((\varphi_t)_{t \geq 0}\). Namely,

**Lemma 5.8**

In the positive drift case \(\beta_0 > 0\) and \(\alpha_0 < 0\).

In the oscillating case \(\beta_0 = 0\) and \(\alpha_0 = 0\).

In the negative drift case \(\beta_0 < 0\) and \(\alpha_0 < 0\).

**Proof:** In the drift cases, \(\alpha_{\max} \neq \beta_{\min}\) and therefore, by Lemma 5.7, \(\beta_0 \in (\alpha_{\max}, \beta_{\min})\). In the positive drift case, by (16), \(\alpha_{\max} = 0\) and \(\beta_{\min} > 0\), and therefore \(\beta_0 > 0\). In the negative drift case, by (16), \(\beta_{\min} = 0\) and \(\alpha_{\max} < 0\), and therefore \(\beta_0 < 0\). Since in both cases the function \(\alpha(\beta)\) has two distinct zeros, its global minimum \(\alpha_0\) is negative.

Finally, in the oscillating case, by (16), \(\alpha_{\max} = \beta_{\min} = 0\) and then \(\beta_0 = 0\). Thus, the function \(\alpha(\beta)\) has exactly one zero at \(\beta = 0\) and, since by 5.6, it attains a global minimum, it follows that \(\alpha(\beta)\) attains its global minimum at \(\beta_0 = 0\) and that \(\alpha_0 = \alpha(\beta_0) = 0\). \(\square\)

**Lemma 5.9** The matrix \(Q^0\) given by (1) is a conservative irreducible \(Q\)-matrix. In addition, if \(\mu^0\) is a vector on \(E\) such that \(\mu^0Q^0 = 0\) then \(\mu^0V^1 = 0\).

**Proof:** Since the matrices \(I\) and \(V\) are diagonal and the vector \(g_0\) is positive, the matrix \(Q^0\) is essentially non-negative. In addition, \(Q^01 = 0\).

By Lemma 5.1, the matrix \((Q - \alpha_0I - \beta_0V)\) is irreducible which implies that the matrix \(e^{t(Q - \alpha_0I - \beta_0V)}\) is positive for all \(t > 0\). Since the vector \(g_0\) is positive, it follows from the definition of \(Q^0\) that \(e^{tQ^0}\) is positive for all \(t > 0\) and that the matrix \(Q^0\) is irreducible.

Let \(g_0^{left}\) be the left Perron-Frobenius eigenvector of the matrix \((Q - \beta_0V)\) and let \(\mu^0\) be a vector on \(E\) with entries \(\mu^0(e) = g_0^{left}(e)g_0(e), e \in E\). Then \(\mu^0Q^0 = 0\) and by Lemmas 5.7 and 5.8 \(\mu^0V^1 = 0\). Since any vector \(\nu\) which satisfies \(\nu Q^0 = 0\) is a constant multiple of \(\mu^0\), the proof of the lemma is complete. \(\square\)

**Lemma 5.10** For \(\alpha \geq 0\), let

\[ V^{-1}(Q - \alpha I) \Gamma_\alpha = \Gamma_\alpha G_\alpha \quad \text{and} \quad V^{-1}(Q^0 - \alpha I) \Gamma^0_\alpha = \Gamma^0_\alpha G^0_\alpha, \]

be the Wiener-Hopf factorisations of \(V^{-1}(Q - \alpha I)\) and \(V^{-1}(Q^0 - \alpha I)\), respectively (for \(\alpha = 0\) we drop the subscript). Then,

\[ G^0_{\alpha - \alpha_0} = G^{-1}_0 (G_\alpha - \beta_0 I) G_0, \quad \text{and} \quad \Gamma^0_{\alpha - \alpha_0} = G^{-1}_0 \Gamma_\alpha G_0, \quad \alpha \geq 0. \]
Proof: By the definition of $Q^0$ and by the Wiener-Hopf factorization of $V^{-1}(Q - \alpha I)$, for every $\alpha > 0$,

$$V^{-1}(Q^0 - (\alpha - \alpha_0)I) = (G_0^{-1}\Gamma_\alpha G_0) (G_0^{-1}(G_\alpha - \beta_0 I)G_0) (G_0^{-1}\Gamma_\alpha^{-1}G_0).$$ \hspace{0.5cm} (18)

Let $G_0^+(\alpha)$ (respectively $G_0^-(\alpha)$) be the restriction of $G_0$ to $E^+ \times E^+$ (respectively $E^- \times E^-$).

Then,

$$G_0^{-1}(G_\alpha - \beta_0 I)G_0 = \begin{pmatrix} (G_\alpha^{-1}G_\alpha^+ - \beta_0 I)G_0^+ & 0 \\ 0 & -(G_\alpha^{-1}G_\alpha^- + \beta_0 I)G_0^- \end{pmatrix}.$$

Suppose that $(G_0^+)^{-1}(G_\alpha^+ - \beta_0 I)G_0^+$ and $(G_0^-)^{-1}(G_\alpha^- + \beta_0 I)G_0^-$ are $Q$-matrices. Then, by Lemma 5.2, (18) is the Wiener-Hopf factorization of $V^{-1}(Q^0 - (\alpha - \alpha_0)I)$ for $\alpha > 0$, and by the uniqueness of the Wiener-Hopf factorization

$$G_{\alpha-\alpha_0} = G_0^{-1}(G_\alpha - \beta_0 I) G_0, \quad \Pi_{\alpha-\alpha_0} = G_0^{-1}\Gamma_\alpha G_0, \quad \alpha \geq 0.$$

Therefore, all we have to prove is that $(G_0^+)^{-1}(G_\alpha^+ - \beta_0 I)G_0^+$ and $(G_0^-)^{-1}(G_\alpha^- + \beta_0 I)G_0^-$ are $Q$-matrices.

Let the function $h$ be defined by $h(e, \varphi, t) = e^{-\alpha_0 t} e^{-\beta_0 e^\varphi} g_0(e)$. Then $h$ is continuously differentiable in $\varphi$ and $t$, and, by (15), it is in the domain of the infinitesimal generator $A$ of the process $(X_t, \varphi_t, t)_{t \geq 0}$ and $Ah = 0$. It follows that the process $(h(X_{t \wedge H_y}, \varphi_{t \wedge H_y}, t \wedge H_y))_{t \geq 0}$ is a positive martingale. By Fatou’s lemma,

$$E_{(e,\varphi)}(e^{-\alpha_0 H_y} e^{-\beta_0 e^\varphi H_y} g_0(X_{H_y})) \leq e^{-\beta_0 e^\varphi} g_0(e),$$

and because $g_0$ is positive, for $\alpha > \alpha_0$,

$$E_{(e,\varphi)}(e^{-\alpha H_y} g_0(X_{H_y})) \leq E_{(e,\varphi)}(e^{-\alpha_0 H_y} g_0(X_{H_y})) \leq e^{-\beta_0(\varphi-y)} g_0(e).$$ \hspace{0.5cm} (19)

By Lemma 5.3, for $\varphi = 0$ and $y > 0$,

$$e^{-\beta_0 y} g_0(e) \geq E_{(e,0)}(e^{-\alpha H_y} g_0(X_{H_y})) = \left( \Pi_{\alpha}^{y} e^{yG_{\alpha}^{-}} g_0^{-} \right),$$

which implies that $e^{y(G_\alpha^+-\beta_0)} g_0^+ \leq g_0^+$. Hence, because

$$\lim_{y \to 0} \frac{e^{y(G_\alpha^+-\beta_0)} g_0^+ - g_0^+}{y} = (G_\alpha^+-\beta_0)g_0^+,$$

$(G_\alpha^+-\beta_0)g_0^+ \leq 0$ and therefore, because $(G_\alpha^+)^{-1}$ is positive,

$$(G_0^+)^{-1}(G_\alpha^+ - \beta_0 I)G_0^+ I^+ = (G_0^+)^{-1}(G_\alpha^+ - \beta_0 I)g_0^+ \leq 0$$

and $(G_0^-)^{-1}(G_\alpha^- + \beta_0 I)G_0^-$ is a $Q$-matrix. It can be proved in the same way that $(G_0^-)^{-1}(G_\alpha^- - \beta_0 I)G_0^-$ is a $Q$-matrix.
Theorem 5.1 For $\alpha \geq 0$, let $\alpha_{\text{max}}(\alpha)$ and $\beta_{\text{min}}(\alpha)$ be the eigenvalues of the matrix $V^{-1}(Q - \alpha I)$ with maximal negative and minimal positive real parts, respectively, and let $f_{\text{max}}(\alpha)$ and $g_{\text{min}}(\alpha)$ be their associated eigenvectors, respectively.

Then, in the oscillating case, there exists $\varepsilon > 0$ such that, for $0 < \alpha < \varepsilon$, and some constants $d_n, n = 2, 3, \ldots$ and $c > 0$,

$$
\alpha_{\text{max}}(\alpha) = -\frac{1}{\sqrt{-\mu V r}} \alpha^{\frac{1}{2}} + d_2 \alpha + d_3 \alpha^{\frac{3}{2}} + \ldots = -\frac{1}{\sqrt{-\mu V r}} \alpha^{\frac{1}{2}} + \Theta_{\text{max}}(\alpha^{\frac{1}{2}})
$$

$$
\beta_{\text{min}}(\alpha) = \frac{1}{\sqrt{-\mu V r}} \alpha^{\frac{1}{2}} + \frac{1}{\sqrt{-\mu V r}} \alpha^{\frac{1}{2}} + \Theta_{\text{min}}(\alpha^{\frac{1}{2}}),
$$

and $|\Theta_{\text{max}}(\alpha^{\frac{1}{2}})| < c \alpha$ and $|\Theta_{\text{min}}(\alpha^{\frac{1}{2}})| < c \alpha$.

The vectors $f_{\text{max}}(\alpha)$ and $g_{\text{min}}(\alpha)$ can be chosen to be

$$
f_{\text{max}}(\alpha) = 1 - \frac{1}{\sqrt{-\mu V r}} \alpha^{\frac{1}{2}} r + \alpha v_2 + \ldots = 1 - \frac{1}{\sqrt{-\mu V r}} \alpha^{\frac{1}{2}} r + \Xi_{\text{max}}(\alpha^{\frac{1}{2}})
$$

$$
g_{\text{min}}(\alpha) = 1 + \frac{1}{\sqrt{-\mu V r}} \alpha^{\frac{1}{2}} r + \alpha w_2 + \ldots = 1 + \frac{1}{\sqrt{-\mu V r}} \alpha^{\frac{1}{2}} r + \Xi_{\text{min}}(\alpha^{\frac{1}{2}}),
$$

where $V^{-1}Qr = 1$, and $|\Xi_{\text{max}}(\alpha^{\frac{1}{2}})| < \alpha v$ and $|\Xi_{\text{min}}(\alpha^{\frac{1}{2}})| < \alpha w$ for some positive vectors $v$ and $w$ on $E$.

In the negative drift case, there exists $\varepsilon > 0$ such that, for $0 < \alpha < \varepsilon$ and some constants $a_n$ and $b_n, n \in \mathbb{N}$,

$$
\alpha_{\text{max}}(\alpha) = \alpha_{\text{max}} + a_1 \alpha + a_2 \alpha^2 + \ldots \quad \text{and} \quad \beta_{\text{min}}(\alpha) = b_1 \alpha + b_2 \alpha^2 + b_3 \alpha^3 + \ldots,
$$

and the vectors $f_{\text{max}}(\alpha)$ and $g_{\text{min}}(\alpha)$ can be chosen to be

$$
f_{\text{max}}(\alpha) = f_{\text{max}} + \alpha v_1 + \alpha^2 v_2 + \ldots \quad \text{and} \quad g_{\text{min}}(\alpha) = 1 + \alpha w_1 + \alpha^2 w_2 + \ldots,
$$

where $v_n$ and $w_n, n \in \mathbb{N}$, are some constant vectors.

The analogous result follows in the positive drift case.

Proof: The eigenvalues of $V^{-1}(Q - \alpha I)$ converge to the eigenvalues of $V^{-1}Q$ as $\alpha \to 0$. Thus, $\alpha_{\text{max}}(\alpha) \to \alpha_{\text{max}}$ and $\beta_{\text{min}}(\alpha) \to \beta_{\text{min}}$ as $\alpha \to 0$.

In the drift cases, by (16), $\alpha_{\text{max}} \neq \beta_{\text{min}}$. Hence, $\alpha_{\text{max}}$ and $\beta_{\text{min}}$ are simple eigenvalues of $V^{-1}Q$ which implies that, for sufficiently small $\alpha > 0$, $\alpha_{\text{max}}(\alpha)$ and $\beta_{\text{min}}(\alpha)$, and also $f_{\text{max}}(\alpha)$ and $g_{\text{min}}(\alpha)$, can be represented by convergent power series (see Wilkinson [5]). In addition, in the positive drift case, $\alpha_{\text{max}} = 0$ and $f_{\text{max}} = 1$ and in the negative drift case $\beta_{\text{min}} = 0$ and $g_{\text{min}} = 1$. Therefore, the part of the theorem for the drift cases is proved.

In the oscillating case, by (16), zero is an eigenvalue of the matrix $V^{-1}Q$ with algebraic multiplicity two. Hence, there exists $\varepsilon > 0$ such that for $0 < |\alpha| < \varepsilon$ there exist two eigenvalues of $V^{-1}(Q - \alpha I)$ which converge to zero as $\alpha \to 0$, and those are $\alpha_{\text{max}}(\alpha)$ and $\beta_{\text{min}}(\alpha)$. In addition, one of the following is valid:
either
\[
\begin{align*}
\alpha_{\max}(\alpha) &= a_1\alpha + a_2\alpha^2 + a_3\alpha^3 + \ldots \\
\beta_{\min}(\alpha) &= b_1\alpha + b_2\alpha^2 + b_3\alpha^3 + \ldots,
\end{align*}
\]
for some constants \(a_k, b_k, k \in \mathbb{N}\), or
\[
\begin{align*}
\alpha_{\max}(\alpha) &= d_1\alpha^\frac{1}{2} + d_2\alpha + d_3\alpha^2 + \ldots \\
\beta_{\min}(\alpha) &= -d_1\alpha^\frac{1}{2} + d_2\alpha - d_3\alpha^2 + \ldots,
\end{align*}
\]
for some constants \(d_k, k \in \mathbb{N}\). We shall show that (20) is not possible.

For any \(\alpha > 0\),
\[
(Q - \alpha_{\max}(\alpha)V)f_{\max}(\alpha) = \alpha f_{\max}(\alpha).
\]

Since by Lemma 5.1, the matrix \((Q - \alpha_{\max}V)\) is irreducible and essentially non-negative and the vector \(f_{\max}(\alpha)\) is positive, it follows that \(\alpha\) is the Perron-Frobenius eigenvalue of \((Q - \alpha_{\max}(\alpha)V)\). Similarly, \(\alpha\) is the Perron-Frobenius eigenvalue of \((Q - \beta_{\min}(\alpha)V)\).

Let \(\beta \in \mathbb{R}\) and consider the matrix \((Q - \beta V)\) and its Perron-Frobenius eigenvalue \(\alpha(\beta)\) and eigenvector \(u(\beta)\). The eigenvalue \(\alpha(\beta)\) is simple and it converges to a simple eigenvalue of the matrix \(Q\) as \(\beta \to 0\). Thus, for \(|\beta| < \delta\),
\[
\begin{align*}
\alpha(\beta) &= c_0 + c_1\beta + c_2\beta^2 + \ldots \\
u(\beta) &= 1 + \beta v_1 + \beta^2 v_2 + \ldots,
\end{align*}
\]
for some constants \(c_k, k \in \mathbb{N} \cup \{0\}\) and some vectors \(v_k, k \in \mathbb{N}\), on \(E\).

Suppose that the process \((\varphi_t)_{t \geq 0}\) oscillates. By Lemmas 5.7 and 5.8 the eigenvalue \(\alpha(\beta)\) attains its global minimum 0 at \(\beta = 0\). Hence, \(\alpha(0) = \frac{d\alpha}{d\beta}(0) = 0\), which gives that \(c_0 = c_1 = 0\), and therefore
\[
\alpha(\beta) = c_2\beta^2 + c_3\beta^3 + c_4\beta^4 + \ldots .
\]

By substituting \(\alpha(\beta)\) and \(u(\beta)\) into the equation
\[
(Q - \beta V)u(\beta) = \alpha(\beta)u(\beta)
\]
and by equating terms in \(\beta\) and \(\beta^2\) on each side of the previous equation, we obtain
\[
V^{-1}Q v_1 = 1 \quad Q v_2 - V v_1 = c_2.1.
\]

It follows that \(c_2 \neq 0\) (if \(c_2 = 0\) then \(V^{-1}Q v_2 = v_1\) which is by Jordan matrix theory not possible since 0 is the eigenvalue of \(V^{-1}Q\) with algebraic multiplicity 2).

Suppose that (20) is true. Then, it follows from (20) and (22) that, for \(|\alpha| < \varepsilon\),
\[
\alpha = \alpha(\alpha_{\max}) = c_2 \alpha_{\max}(\alpha)^2 + c_3 \alpha_{\max}(\alpha)^3 + \ldots
\]
\[
= c_2(a_1\alpha + a_2\alpha^2 + \ldots)^2 + c_3(a_1\alpha + a_2\alpha^2 + \ldots)^3 + \ldots
\]
\[
= c_2a_1^2\alpha^2 + \text{const}.\alpha^3 + \ldots,
\]

18
which is not possible for every $|\alpha| < \varepsilon$. Hence, (20) is not true and thus (21) holds.

Substituting $\alpha_{\max}(\alpha)$ and $\beta_{\min}(\alpha)$ from (21) into (24) gives $d_1^2 = \frac{1}{c_2}$. By Lemmas 5.7 and 5.8, $\alpha(0) = 0$ is the minimum of the function $\alpha(\beta)$ which implies that $\alpha(\beta) > 0$ for all $\beta \in \mathbb{R}$, and, by (24), that $c_2 > 0$. By multiplying second equality in (25) by $\mu$ from the left, we obtain (because $\mu 1 = 1$), $c_2 = -\frac{\mu V v_1}{\mu 1} = -\mu V v_1$. Therefore, the statement in the theorem follows from (21) and (23).
