Introduction

Pursuit-Evasion games with state constraints

Convergence of the Fully Discrete Scheme

Numerical experiments without state constraints

Numerical experiments with state constraints

Fast Marching Methods

Introduction

Our approach is based on the Dynamic Programming Principle which allows to derive a nonlinear first order partial differential equation describing the value function of the game (or the upper/lower value function).

The theory of viscosity solutions gives the correct framework to characterize the value function (or its upper/lower version) as the unique weak solution of the Isaacs equation.

This characterization has been used also to construct numerical schemes for the value function and to synthetize optimal feedbacks.

Introduction

Our approach is based on the Dynamic Programming Principle which allows to derive a nonlinear first order partial differential equation describing the value function of the game (or the upper/lower value function).

The theory of viscosity solutions gives the correct framework to characterize the value function (or its upper/lower version) as the unique weak solution of the Isaacs equation.

This characterization has been used also to construct numerical schemes for the value function and to synthetize optimal feedbacks.

Hamilton-Jacobi-Isaacs equation

$$v(x) + \min_{b \in B} \max_{a \in A} \{-f(x, a, b) \cdot \nabla v(x)\} - 1 = 0 \quad x \in \overline{\mathbb{R}^n} \setminus \mathcal{T}$$

where *A*, *B* are the admissible controls for the first and for the second player, *f* is the vectorfield and T is the (given) target set.

Typically the HJI equation is complemented with Dirichlet boundary conditions

$$v(x) = g(x)$$
 for $x \in \partial T$

Uniqueness of viscosity solutions holds under rather general assumptions (Evans-Souganidis, Bardi). Another approach have been proposed by A. Subbotin (minmax solutions). This approach has been used successfully for problems without state constraints and has produced accurate results for 2-dimensional games.

However its extension to games with state constraints is non trivial and few results are available, mainly via the viability approach proposed by Aubin (viability kernel solutions).

Pursuit-Evasion games with state constraints in \mathbb{R}^{2N}

$$\begin{cases} \dot{y}(t) = f(y(t), a(t), b(t)), & t > 0\\ y(0) = x \end{cases}$$

where
$$\mathbf{x} = (\mathbf{x}_P, \mathbf{x}_E)$$
, $\mathbf{y} = (\mathbf{y}_P, \mathbf{y}_E)$, $\mathbf{a} \in \mathbf{A}, \mathbf{b} \in \mathbf{B}$
 $f(\mathbf{x}, \mathbf{a}, \mathbf{b}) = f(\mathbf{x}_P, \mathbf{x}_E, \mathbf{a}, \mathbf{b}) = \begin{pmatrix} f_P(\mathbf{x}_P, \mathbf{a}) \\ f_E(\mathbf{x}_E, \mathbf{b}) \end{pmatrix}$, $f_P, f_E \in \mathbb{R}^N$

State Constraints $y_P(t) \in \overline{\Omega}_1, \quad y_E(t) \in \overline{\Omega}_2$

Target

 $\mathcal{T} = \{ (x_P, x_E) \in \mathbb{R}^{2N} : |x_P - x_E| \le \varepsilon \}, \quad \varepsilon \ge 0$

Pursuit-Evasion games with state constraints in \mathbb{R}^{2N}

$$\begin{cases} \dot{y}(t) = f(y(t), a(t), b(t)), \quad t > 0\\ y(0) = x \end{cases}$$

where
$$x = (x_P, x_E)$$
, $y = (y_P, y_E)$, $a \in A, b \in B$
 $f(x, a, b) = f(x_P, x_E, a, b) = \begin{pmatrix} f_P(x_P, a) \\ f_E(x_E, b) \end{pmatrix}$, $f_P, f_E \in \mathbb{R}^N$

State Constraints $y_P(t) \in \overline{\Omega}_1, \quad y_E(t) \in \overline{\Omega}_2$

Target

 $\mathcal{T} = \{ (x_P, x_E) \in \mathbb{R}^{2N} : |x_P - x_E| \le \varepsilon \}, \quad \varepsilon \ge 0$

Pursuit-Evasion games with state constraints in \mathbb{R}^{2N}

$$\begin{cases} \dot{y}(t) = f(y(t), a(t), b(t)), \quad t > 0\\ y(0) = x \end{cases}$$

where
$$\mathbf{x} = (\mathbf{x}_P, \mathbf{x}_E)$$
, $\mathbf{y} = (\mathbf{y}_P, \mathbf{y}_E)$, $\mathbf{a} \in A, \mathbf{b} \in B$
 $f(\mathbf{x}, \mathbf{a}, \mathbf{b}) = f(\mathbf{x}_P, \mathbf{x}_E, \mathbf{a}, \mathbf{b}) = \begin{pmatrix} f_P(\mathbf{x}_P, \mathbf{a}) \\ f_E(\mathbf{x}_E, \mathbf{b}) \end{pmatrix}$, $f_P, f_E \in \mathbb{R}^N$

State Constraints $y_P(t) \in \overline{\Omega}_1, \quad y_E(t) \in \overline{\Omega}_2$

Target

 $\mathcal{T} = \{ (\mathbf{x}_{\mathcal{P}}, \mathbf{x}_{\mathcal{E}}) \in \mathbb{R}^{2N} : |\mathbf{x}_{\mathcal{P}} - \mathbf{x}_{\mathcal{E}}| \leq \varepsilon \}, \quad \varepsilon \geq \mathbf{0}$

The Tag-Chase game with state constraints

Two boys *P* and *E* which run one after the other in the same 2-dimensional domain (courtyard), so that the game is set in $\overline{\Omega} = \overline{\Omega}_1^2 \subset \mathbb{R}^4$.

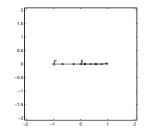

P and *E* can run in every direction with velocity V_P and V_E respectively.

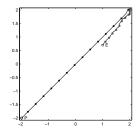

$$\begin{cases} \dot{x}_P = V_P a & a \in B_2(0,1) \\ \dot{x}_E = V_E b & b \in B_2(0,1) \end{cases}$$

Pursuit-Evasion games with state constraints

A simple example

◆ロ〉 ◆母〉 ◆臣〉 ◆臣〉 ○臣 ● 今々で

Optimal exploitation of natural resources (Jorgensen)

Let us consider a common property fishery. m(t) = biomass of a particular stock of fish at time t Assume that the stock is harvested by two fishermen A and B. Fish has a natural growth, which follows the logistic function. State dynamics

$$\dot{m}(t) = m(1-m) - (\alpha(t) + \beta(t))$$

 α and β are the controls of the two players, which correspond to their harvest rate.

We impose two two natural constraints:

 $0 \le \alpha(t), \beta(t) \le C_{max}$ and $m(t) \ge 0$ for any t

Under these hypotheses, we have $m \in [0, 1]$ for any *t*.

Optimal allocation of natural resources

Each fisherman wants to maximize his payoff

$$J_{\mathcal{A}}(\alpha) = \int_{0}^{\infty} \left(-\frac{1}{\alpha(s)} \right) e^{-\lambda s} ds, \quad J_{\mathcal{B}}(\beta) = \int_{0}^{\infty} \left(-\frac{1}{\beta(s)} \right) e^{-\lambda s} ds$$

where $\lambda \in (0, 1)$.

Every fisherman would like to choose its harvest rate as large as possible, but he must be careful not to drive the stock to zero because then he has to stop fishing.

WARNING: for m = 0, the constraint $m \ge 0$ imposes $\alpha = 0$ and $\beta = 0$.

Pursuit-Evasion games with state constraints

Isaacs equation

T(x) := capture time under optimal (non-anticipating) strategies of both players.

THEOREM (Koike, 1995) $v(x) = 1 - e^{-T(x)}$ is the unique viscosity solution of

$$\begin{cases} v(x) + \min_{b \in B(x)} \max_{a \in A(x)} \{-f(x, a, b) \cdot \nabla v(x)\} - 1 = 0 & x \in \overline{\Omega} \setminus \mathcal{T} \\ v(x) = 0 & \text{on } \partial \mathcal{T} \end{cases}$$

(日)

For
$$A(x) = A$$
 and $B(x) = B$
 $v(x) = 1 - e^{-T(x)}$ is the unique viscosity solution of
Hamilton-Jacobi-Isaacs equation

$$\begin{cases} v(x) + \min_{b \in B} \max_{a \in A} \{-f(x, a, b) \cdot \nabla v(x)\} - 1 = 0, \quad x \in \overline{\Omega} \setminus \mathcal{T} \\ v(x) = 0 \text{ on } \partial \mathcal{T} \end{cases}$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● のへぐ

Fully discrete scheme (without constraints)

Let the constraint be given by $\Omega=\Omega_1\cap\Omega_2.$ We define

$$\beta = \mathbf{e}^{-h}$$

$$I_{in} = \{i : \mathbf{x}_i \in \Omega \setminus \mathcal{T}\}$$

$$I_{\mathcal{T}} = \{i : \mathbf{x}_i \in \mathcal{T} \cap \Omega\}$$

$$I_{out_1} = \{i : \mathbf{x}_i \notin \Omega_2\}$$

$$I_{out_2} = \{i : \mathbf{x}_i \notin \Omega_2 \setminus \Omega\}$$

Fully discrete scheme (without constraints)

The discretization in time and space leads to a fully discrete scheme

$$w(x_i) = \max_{b \in B} \min_{a \in A} [\beta w(x_i + hf(x_i, a, b)] + 1 - \beta \text{ for } i \in I_{in}$$

$$w(x_i) = 1 \quad \text{for } i \in I_{out_2}$$

$$w(x_i) = 0 \quad \text{for } i \in I_T \cup I_{out_1}$$

Fully discrete scheme (without constraints)

Theorem The operator $S : [0, 1]^L \rightarrow [0, 1]^L$. S satisfies the following properties:

> $U \le V \Rightarrow S(U) \le S(V)$ S is a contraction map.

Let U^* be the unique fixed point, we define

$$w(x_i) = U_i^*$$
 $\forall i$
 $w(x) = \sum_j \lambda_{ij}(a, b) w(x_j)$ (linear interpolation)

Convergence (without constraints)

Naturally w depends on the discretization steps, h and k.

Theorem

Let T be the closure of an open set with Lipschitz boundary, "diam $\Omega \to +\infty$ " and v continuous. Then

 $w^{h,k} \rightarrow v$ on compact sets of \mathbb{R}^N

(日) (日) (日) (日) (日) (日) (日) (日)

for $h \to 0^+$ and $\frac{k}{h} \to 0^+$.

Convergence: discontinuous value

Let w_n^{ε} be the sequence generated by the numerical scheme with target $T_{\varepsilon} = \{ x : d(x, T) \le \varepsilon \}$

Theorem For all x there exists the limit

$$\overline{w}(x) = \lim_{\substack{\varepsilon \to 0^+ \\ n \to +\infty \\ n \ge n(\varepsilon)}} w_n^{\varepsilon}(x)$$

and it coincides with the lower value V of the game with target $\mathcal T$, i.e.

$$\overline{w} = V$$

The convergence is uniform on every compact set where V is continuous.

Time-discrete scheme for P-E games with SC

Definition: Admissible controls

$$egin{aligned} \mathcal{A}(y) &= \{ a \in \mathcal{A} : \exists \ r > 0 \ ext{such that} \ y_{\mathcal{P}}(t; y'_{\mathcal{P}}, a) \in \overline{\Omega}_1 \ & ext{for} \ t \in [0, r] \ ext{and} \ y'_{\mathcal{P}} \in \mathcal{B}(y_{\mathcal{P}}, r) \cap \overline{\Omega}_1 \}, \end{aligned}$$

$$B(y) = \{b \in B : \exists r > 0 \text{ such that } y_E(t; y'_E, b) \in \overline{\Omega}_2 \$$
for $t \in [0, r]$ and $y'_E \in B(y_E, r) \cap \overline{\Omega}_2\}.$

A(x) and B(x) are the admissible controls sets at x w.r. t. the constraints.

Time-discrete scheme for P-E games with SC

Definition: Admissible controls (discrete time version)

$$\begin{split} A_h(x) &:= \left\{ a \in A : x_P + hf_P(x_P, a) \in \overline{\Omega}_1 \right\}, \qquad x \in \overline{\Omega} \\ B_h(x) &:= \left\{ b \in B : x_E + hf_E(x_E, b) \in \overline{\Omega}_2 \right\}, \qquad x \in \overline{\Omega}. \end{split}$$

$$\begin{cases} v_h(x) = \max_{b \in B_h(x)} \min_{a \in A_h(x)} \left\{ \beta v_h(x + hf(x, a, b)) \right\} + 1 - \beta \quad x \in \overline{\Omega} \setminus \mathcal{T} \\ v_h(x) = 0 \qquad \qquad x \in \mathcal{T} \end{cases}$$

where $\beta = e^{-h}$.

◆□▶ ◆□▶ ◆三▶ ◆三▶ ○○ ○○○

Fully-discrete scheme for P-E games with SC

We build a regular triangulation of $\overline{\Omega}$ denoting by: *X* the set of its nodes x_i , i = 1, ..., L $k := \max_j \{ diam(S_j), S_j simplex of the triangulation \}$

$$\begin{cases} v_h^k(x_i) = \max_{b \in B_h(x_i)} \min_{a \in A_h(x_i)} \left\{ \beta v_h^k(x_i + hf(x_i, a, b)) \right\} + 1 - \beta & x_i \in (X \setminus T) \\ v_h^k(x_i) = 0 & x_i \in T \cap X \\ v_h^k(x) = \sum_j \lambda_j(x) v_h^k(x_j), \quad 0 \le \lambda_j(x) \le 1, \quad \sum_j \lambda_j(x) = 1 & x \in \overline{\Omega} \end{cases}$$

Convergence of the Fully Discrete Scheme

Discrete Reachable Sets

Definition $\mathcal{R}_0 := \mathcal{T}$

$$\mathcal{R}_n := \left\{ x \in \overline{\Omega} \setminus \bigcup_{j=0}^{n-1} \mathcal{R}_j : \text{ for all } b \in B_h(x) \text{ there exists} \\ \hat{a}_x(b) \in A_h(x) \text{ such that } x + hf(x, \hat{a}_x(b), b) \in \mathcal{R}_{n-1} \right\}, \quad n \ge 1.$$

▲□▶▲圖▶▲≣▶▲≣▶ ≣ のQ@

Main result

Theorem

Let Ω be an open bounded set, *f* be continuous and Lipschitz continuous w.r. t. *x*. Assume *P* always reaches *E* and let $\min_{x,a,b} |f(x, a, b)| \ge f_0 > 0$ and $0 < k \le f_0 h$. Then, we have:

a)
$$v_h(x) \le v_h(y)$$
, for any $x \in \bigcup_{j=0}^n \mathcal{R}_j$, for any $y \in \overline{\Omega} \setminus \bigcup_{j=0}^n \mathcal{R}_j$;
b) $v_h(x) = 1 - e^{-nh}$, for any $x \in \mathcal{R}_n$;
c) $v_h^k(x) = 1 - e^{-nh} + O(k) \sum_{j=0}^n e^{-jh}$ for any $x \in \mathcal{R}_n$;
d)

$$|v_h(x)-v_h^k(x)|\leq rac{Ck}{1-e^{-h}}\,,\quad ext{ for any }x\in\overline{\Omega}.$$

for some positive constant C > 0.

Convergence for P-E games with SC

Coupling the two results we can prove that our approximation scheme converges to the value function.

Cristiani, F. (2006)

Under the assumptions of our main result, $v_h^k \rightarrow v_h$

Bardi, Koike, Soravia (2000)

Under regularity assumptions on the sets of constraints, $v_h \rightarrow v$

₩

Under the above assumptions, $v_h^k \to v$ uniformly for $k = O(h^{1+\alpha})$ and $h \to 0$.

Feedback controls for games

The algorithm computes an approximate optimal control couple (a^*, b^*) at each point of the grid. By *w* we can also compute an approximate optimal feedback at every point of Q.

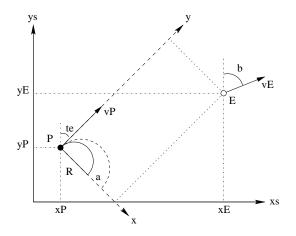

$$(a^{*}(x), b^{*}(x)) \equiv \operatorname{argminmax}\{e^{-h}w(x + hf(x, a, b))\} + 1 - e^{-h}$$

In case of multiple solutions we can select a unique couple, e.g. minimizing two convex functionals.

We can also introduce an inertia criterium to stabilize the trajectories, i.e. if a at step n + 1 the set of optimal couples contains (a_n^*, b_n^*) we keep it.

Numerical experiments without state constraints

Solution of the fishery game (symmetric)

Considering the symmetry of the problem, one possibility is that they make an agreement and we expect the same optimal strategy for the two players.

In this case we can consider the two players as a unique entity and deal with a standard infinite-horizon optimal control problem.

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のので

Solution of the fishery game (symmetric)

We solve numerically the HJB equation

$$\lambda v(x) + \max_{a \in (0, C_{max}]} \{ -f(x, a) \cdot \nabla v(x) - \ell(x, a) \} = 0, \quad x \in [0, 1]$$

where

$$f(x, a) = x(1 - x) - a$$
 and $\ell = 1/a$
the new cost $\widehat{J} = \int_0^\infty \ell(m(s), \alpha(s)) e^{-\lambda s} ds$ must be minimized.

Once the value function v is computed, the optimal control in feedback form and the optimal trajectory are reconstructed

-Numerical experiments without state constraints

Solution of the fishery game (symmetric)

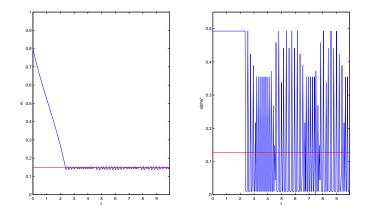

Figure: Optimal trajectory (left) and optimal feedback control (right)

・ロト・日本・日本・日本・日本

Numerical experiments without state constraints

Solution of the fishery game (asymmetric)

In order to avoid the state constraint $m \ge 0$, and we introduce an asymmetry in the problem. we slightly modify the state dynamics

$$\dot{m}(t) = m(1-m) - (\alpha(t) + \beta(t))m(t).$$

Here the two controls represent the "fishing power" used by the two players. We define the cost functional in such a way the problem can be seen as a two-player zero-sum differential game,

$$J(\alpha,\beta) = \int_0^\infty e^{-\lambda s} \Big((\beta m - c_B \beta) - (\alpha m - c_A \alpha) \Big) ds$$

with $0 \le c_A$, $c_B \le 1$.

・ロト・西ト・山田・山田・山下

Numerical experiments without state constraints

Solution of the fishery game (asymmetric)

Player B wants to maximize J, whereas player A wants to minimize it.

 βm (resp., αm) is proportional to the gain of player *B* (resp., player *A*).

 $c_B\beta$ (resp., $c_A\alpha$) represents the cost paid by player *B* (resp., player *A*) to go fishing, we assume that this cost is linear w.r.t. the control variable.

Note that when *m* becomes too small, fishermen have no interest to fish, since the cost overcomes the gain.

Numerical experiments without state constraints

Solution of the fishery game (asymmetric) We solve numerically the HJI equation

 $\lambda v(x) + \min_{b \in [0, C_{max}]} \max_{a \in [0, C_{max}]} \left\{ -f(x, a, b) \cdot \nabla v(x) - \ell(x, a, b) \right\} = 0$

for $x \in [0, 1]$ where

$$f(x,a) = x(1-x) - (a+b)x$$
$$\ell(x,a,b) = (bx - c_Bb) - (ax - c_Aa)$$

If $c_A = c_B$, the game is symmetric and the optimal value for *J* is 0.

If it is not symmetric, we a more interesting situation.

Choosing $c_A = 0.05$, $c_B = 0.025$, $C_{max} = 1$, $\lambda = 0.7$, and m(0) = 0.6, the second player (the most efficient one) is able to eliminate player *A* from the competition, leading the state below the threshold of the positive gain for its competitor.

Numerical experiments without state constraints

Solution of the fishery game (asymmetric)

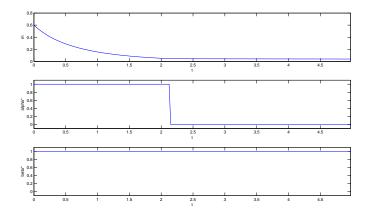

Figure: Optimal trajectory (above) and optimal controls (center and below)

The Tag-Chase game with state constraints

We consider two boys *P* and *E* which run one after the other in the same 2-dimensional domain, so that the game is set in $\overline{\Omega} = \overline{\Omega}_1^2 \subset \mathbb{R}^4$. *P* and *E* can run in every direction with velocity V_P and V_E respectively.

$$\left\{ egin{array}{ll} \dot{x}_{\mathcal{P}} = V_{\mathcal{P}} \, a & a \in B_2(0,1) \ \dot{x}_{\mathcal{E}} = V_{\mathcal{E}} \, b & b \in B_2(0,1) \end{array}
ight.$$

Numerical experiments without state constraints

Capturability in Tag-Chase game

THEOREM

Let the target be

$$\mathcal{T} = \{ (\mathbf{x}_{\mathcal{P}}, \mathbf{x}_{\mathcal{E}}) \in \mathbb{R}^4 : |\mathbf{x}_{\mathcal{P}} - \mathbf{x}_{\mathcal{E}}| \leq \varepsilon \} \,, \qquad \varepsilon \geq \mathbf{0}.$$

and Ω_1 an open bounded set. Then,

• if $V_P > V_E$ then the capture time T is finite and bounded by

$$T(\mathbf{x}_{\mathcal{P}},\mathbf{x}_{\mathcal{E}}) \leq \frac{|\mathbf{x}_{\mathcal{P}}-\mathbf{x}_{\mathcal{E}}|}{|\mathbf{v}_{\mathcal{P}}-\mathbf{v}_{\mathcal{E}}|}$$

If V_P = V_E, ε > 0 and Ω₁ is convex then the capture time T is finite.

<日 > < 同 > < 目 > < 目 > < 目 > < 目 > < 0 < 0</p>

Numerical experiments with state constraints

The computation of the value function has been done in \mathbb{R}^4 since reduced coordinates can not be applied in the constrained problem.

We have exploited the symmetries in the Tag-Chase game and used a fast projection algorithm to interpolate in \mathbb{R}^4 (standard linear interpolation is too expensive).

The synthesis of optimal controls in $\overline{\Omega} \setminus \mathcal{T}$ has been computed by the value function as

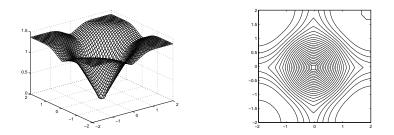

$$(a^*, b^*) = \operatorname{Arg}\max_{b \in B_h(x)} \min_{a \in A_h(x)} \left\{ \beta v_h(x + hf(x, a, b)) \right\} + 1 - \beta$$

Buffered FM Algorithm for differential games with state constraints

The L^1 error is computed with respect to the solution of the iterative algorithm rather than the exact solution. 2x2 controls, $tol = 10^{-6}$.

method	Δx	L ¹ error	CPU time (sec)
SL (70 it)	0.08	-	21.5
BFM	0.08	0.002	9.16
FM-SL	0.08	0.23	1.59
SL (130 it)	0.04	-	157
BFM	0.04	0.002	60
FM-SL	0.04	0.42	6.17
