A CP violation measurement of B_s mesons at ATLAS and the LHC

Adam Barton
ATLAS Collaboration

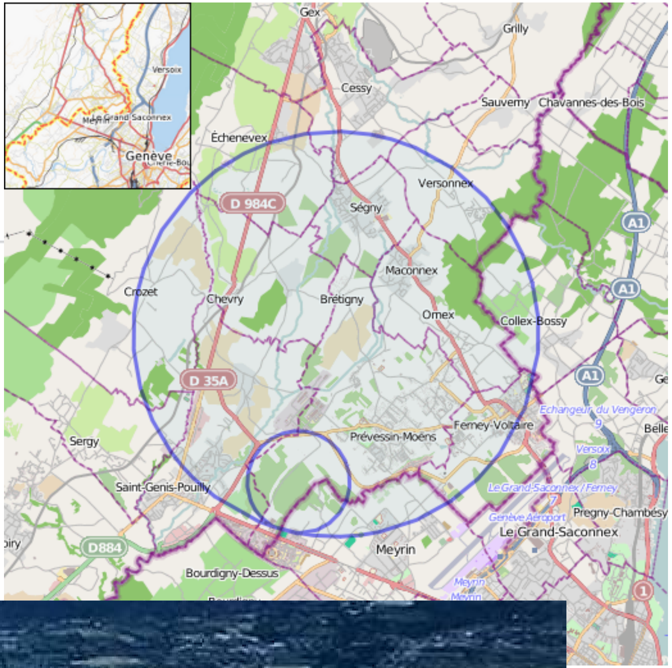
The LHC

The large hadron collider is the world's largest and highest energy synchrotron collider in the world.

It is built and run by CERN (the European/Everyone Organization for Nuclear Research)

It can collide protons at energies of 14 TeV, (currently running at 13TeV

It is located in a 27 kilometer tunnel under Geneva near the Jura mountains.



The ATLAS (A Toroidal LHC ApparatuS) detector

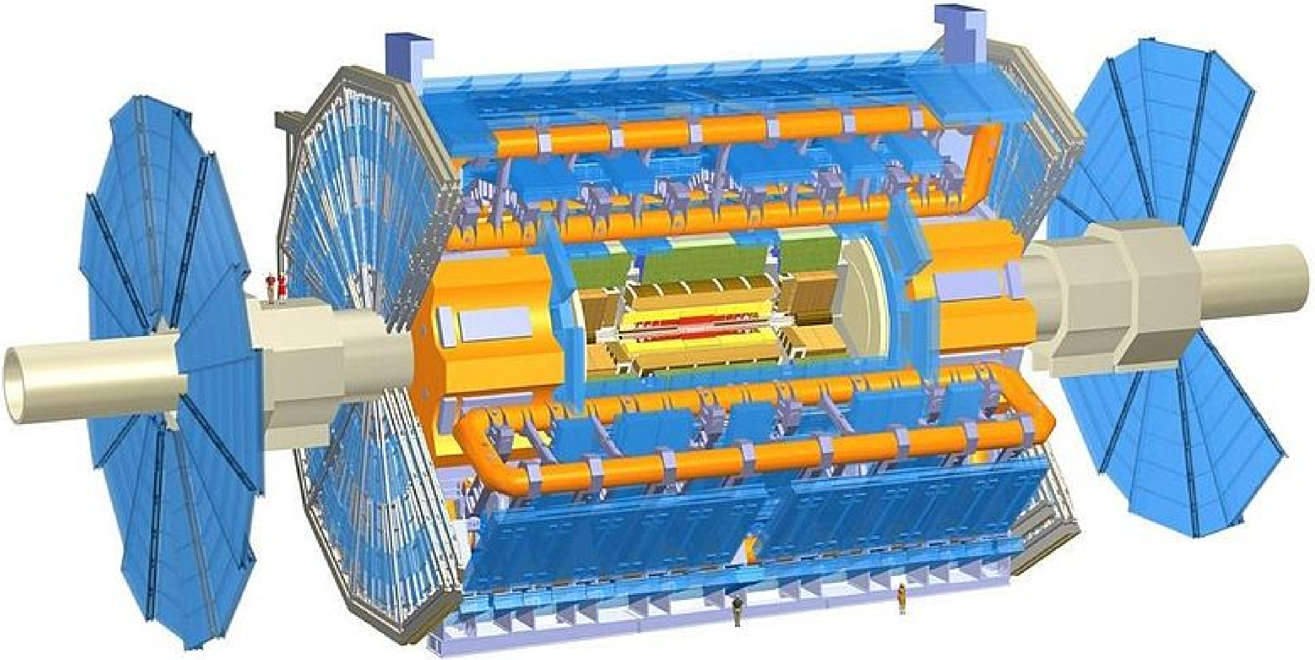
ATLAS is a 45 by 50 metres in

Muon Spectrometer:
- (1) Monitored Drift Tube
- (2) Thin Gap Chamber

Magnet system:
- (3) End-Cap Toroid Magnet
- (4) Barrel Toroid Magnet

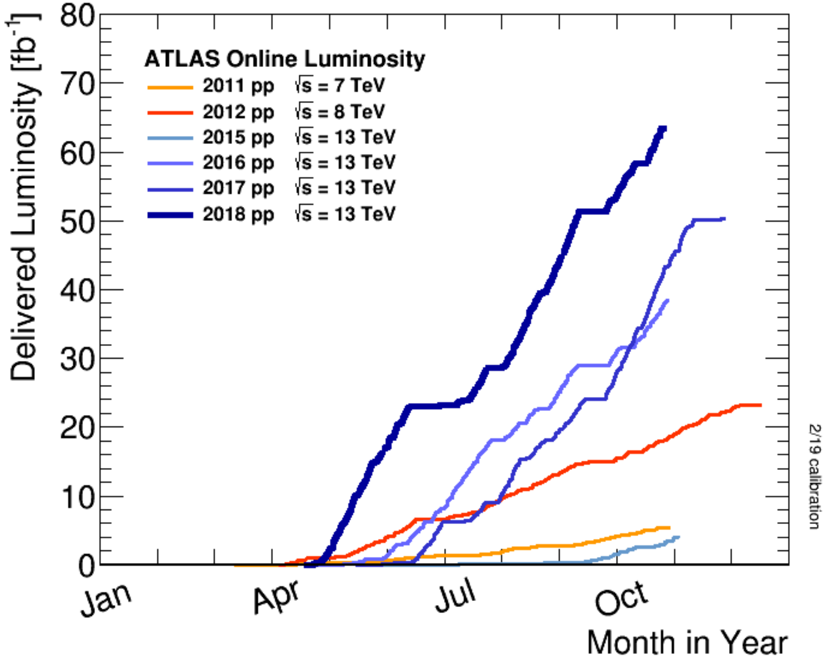
Inner Detector:
- (5) Transition Radiation Tracker
- (6) Semi-Conductor Tracker
- (7) Pixel Detector

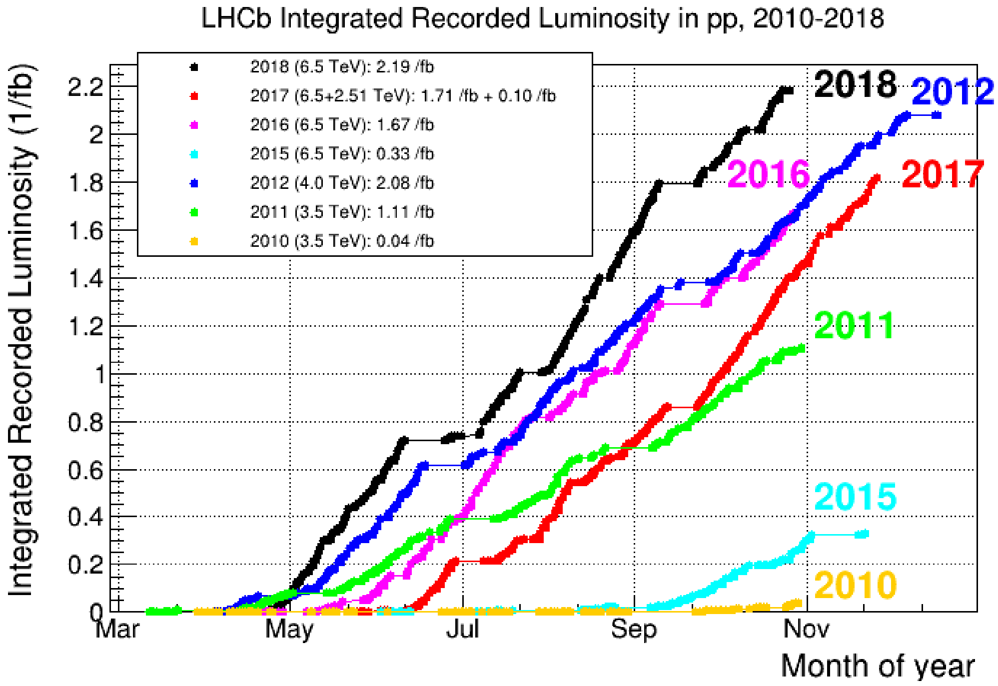
Calorimeters:
- (8) Electromagnetic Calorimeter
- (9) Hadronic Calorimeter



At the start of run 2 (2015) an insertable B-layer was installed to give better vertex and lifetime resolution

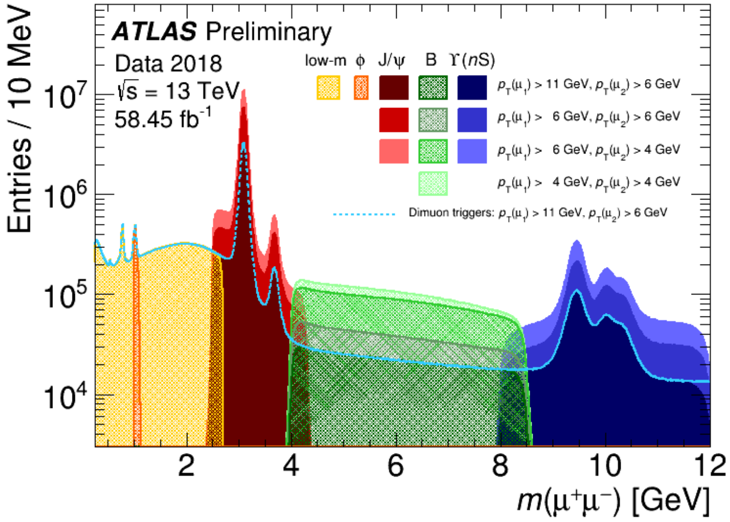
Data Collection





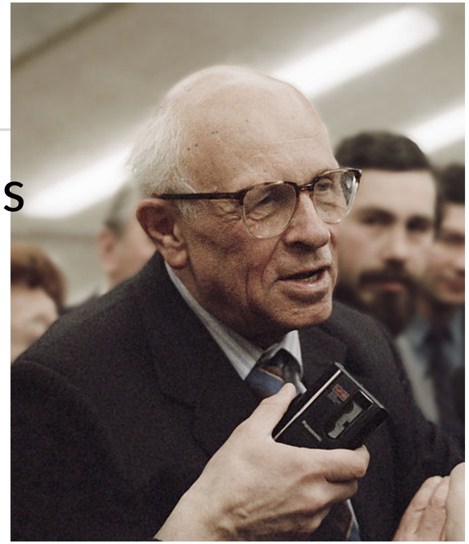
B-physics and Light-States

- ATLAS B-physics and Light-States programme:
  - Comprehensive measurements across a variety of decay modes:
    - Precise property measurements including CPV (Bs->J/ψ φ)
    - Cross-section measurements including Quarkonium
    - Rare decay processes; e.g FCNC $B_{(s,d)} \rightarrow \mu\mu$
    - Spectroscopy, exotic states (e.g pentaquarks)
    - Charged lepton flavour violation (τ -> 3μ)



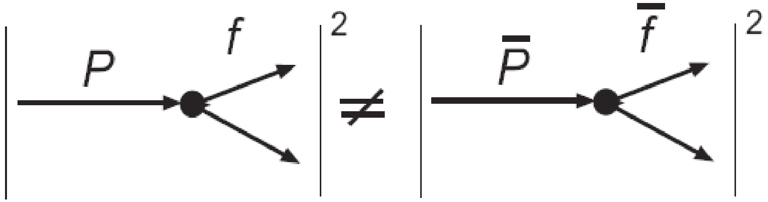
- Typically rely on low-pT di-muon signatures.

Introduction to the CP violation

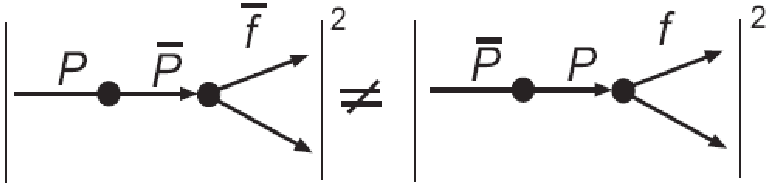


- Charge Parity (CP) symmetries mean that particle interactions should produce matter and antimatter in equal quantities
- In 1967 Soviet Nuclear Physicist Andrei Sakharov proposed CP violation:
  - Since the observed universe seems devoid of stable antimatter there must be baryon number violating transitions in particle physics.
  - CP has to be violated otherwise there would be equal amounts of anti matter
  - CP violations must occur during interactions and not in thermal equilibrium

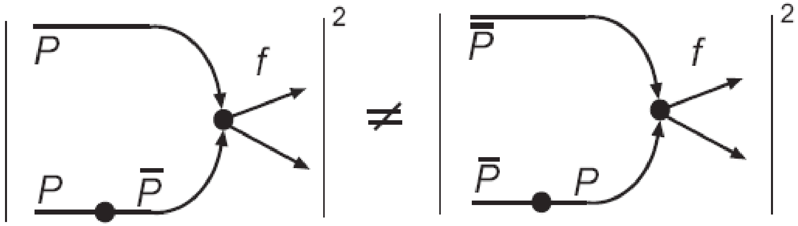
3 Types of CP violation



(a) Direct CP violation.



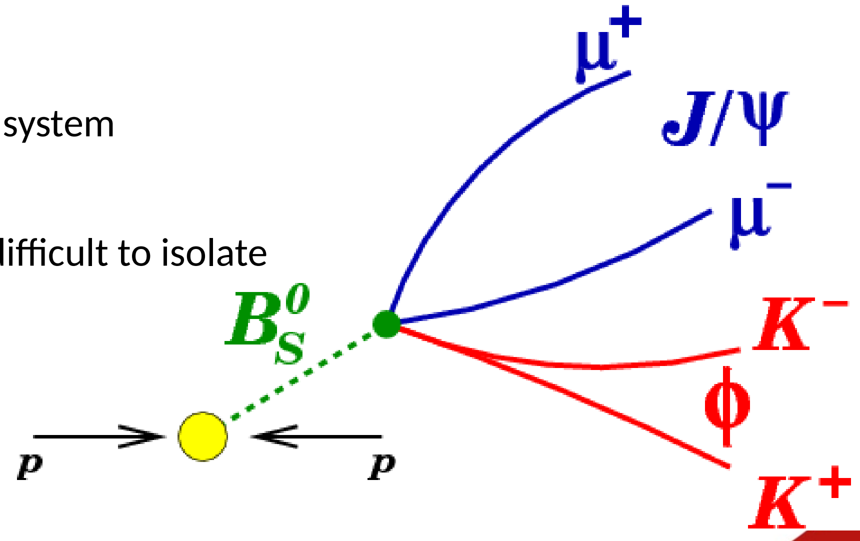
(b) CP violation in mixing.



(c) CP violation in interference.

Exclusive decay chain

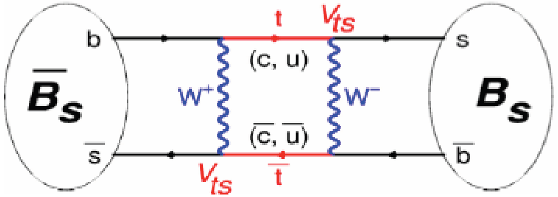
- While φ_s can be accessed a number of ways the easiest way at ATLAS is through the exclusive decay $B_s \rightarrow J/\psi\ \phi$ where
  - $J/\psi \rightarrow \mu^+\mu^-$ selected nicely from the muon system
  - $\phi \rightarrow K^+\ K^-$ ATLAS has no particle ID so this is difficult to isolate

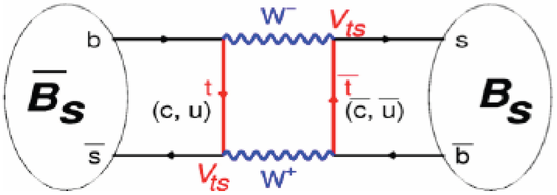


CP Violation in neutral B_s system

Mixing of flavour eigenstates are governed by:

$$i\frac{d}{dt}\begin{pmatrix} B_s^0(t) \\ \overline{B}_s^0(t) \end{pmatrix} = H \begin{pmatrix} B_s^0(t) \\ \overline{B}_s^0(t) \end{pmatrix} \equiv \Bigg[\underbrace{\begin{pmatrix} M_0 & M_{12} \\ M_{12}^* & M_0 \end{pmatrix}}_{\text{mass matrix}} - \frac{i}{2}\underbrace{\begin{pmatrix} \Gamma_0 & \Gamma_{12} \\ \Gamma_{12}^* & \Gamma_0 \end{pmatrix}}_{\text{decay matrix}}\Bigg]\begin{pmatrix} B_s^0(t) \\ \overline{B}_s^0(t) \end{pmatrix}$$



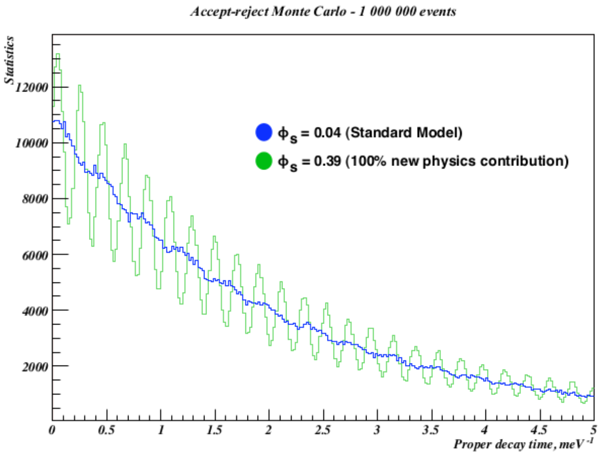


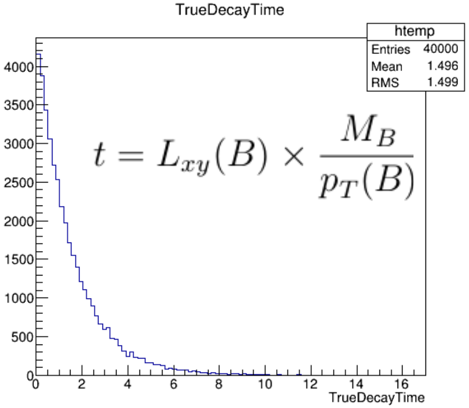
- The mass eigenstates

$$|B_s^H\rangle = p\,|B_s^0\rangle - q\,|\bar{B}_s^0\rangle$$
$$|B_s^L\rangle = p\,|B_s^0\rangle + q\,|\bar{B}_s^0\rangle$$

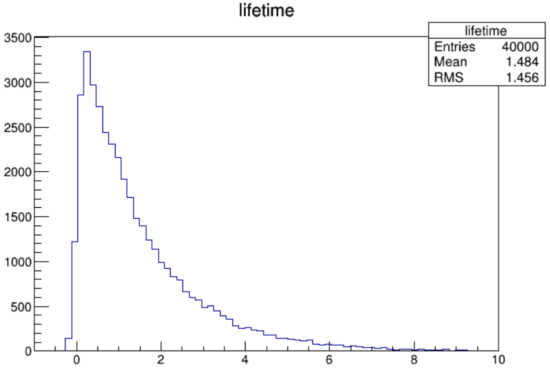
- $\Delta m_S = m_H - m_L \approx 2|M_{12}|$
- $\boldsymbol{\varphi_S}^{SM} = \arg(-M_{12}/\Gamma_{12}) \approx -0.04$ - CP violating phase
- $\boldsymbol{\Gamma}$ is the average lifetime of the two states $(\Gamma_L+\Gamma_H)/2$
- $\boldsymbol{\Delta\Gamma} = \Gamma_L - \Gamma_H \approx 2\,|\Gamma_{12}|\cos(2\,\varphi_S^{SM})$ – Can be considered the difference of the two lifetime states

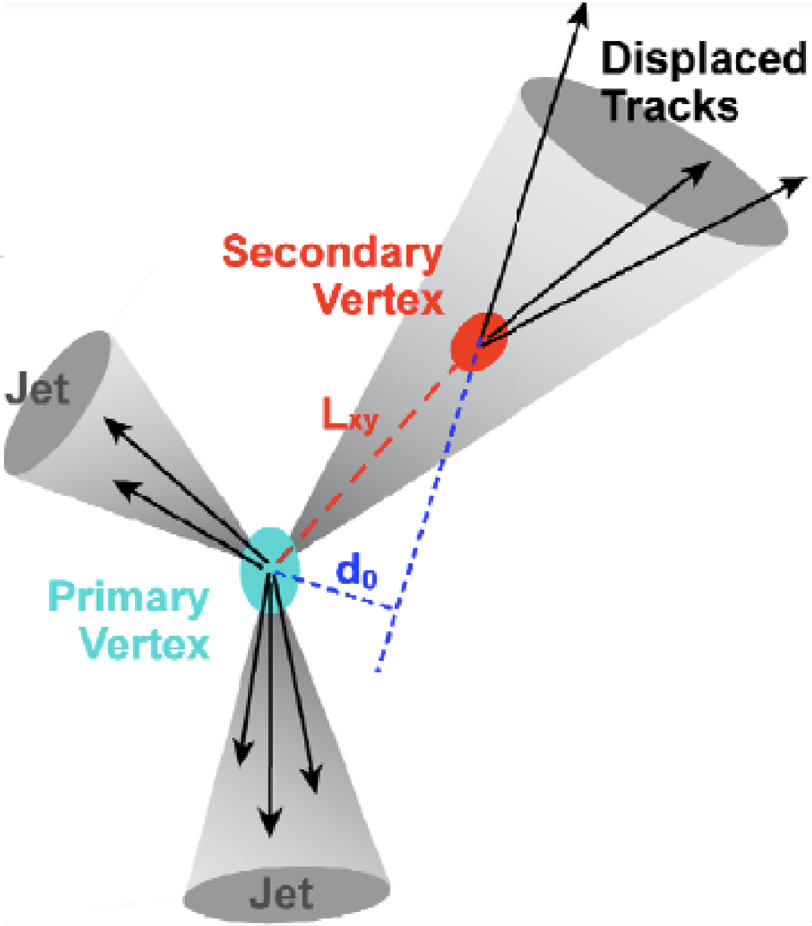
Measuring a particle lifetime





$$t = L_{xy}(B) \times \frac{M_B}{p_T(B)}$$

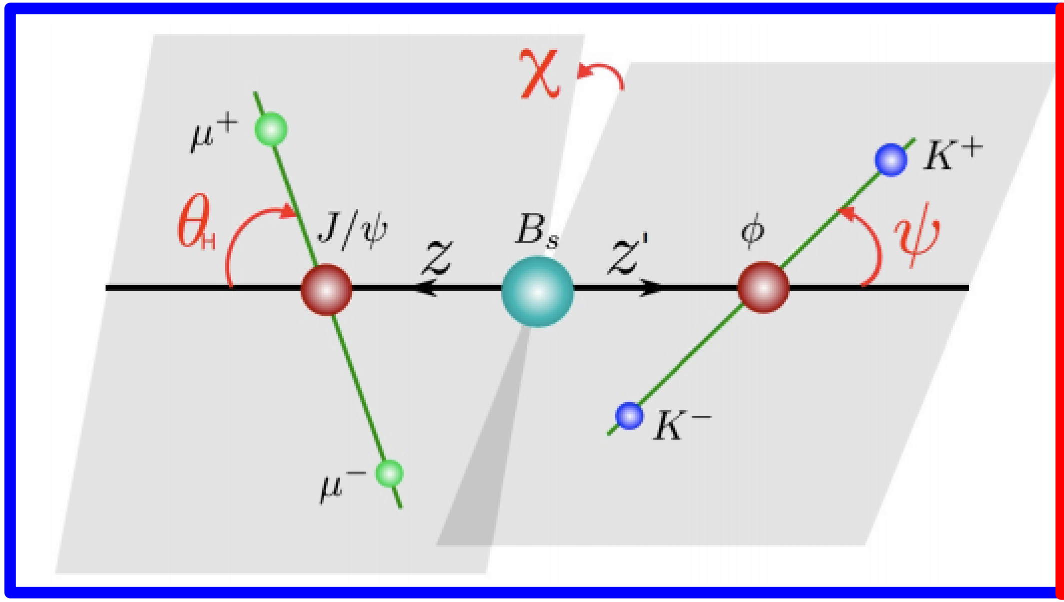




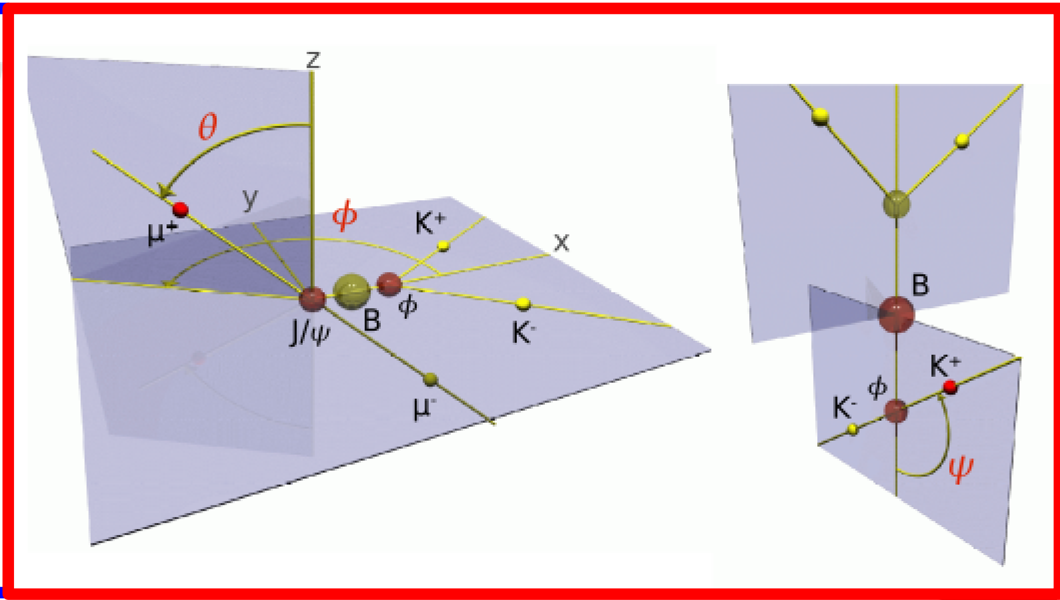
Angular Systems for Bs→ J/ψ ϕ

- You can access the key physical variables for this decay using one of 2 angular definitions

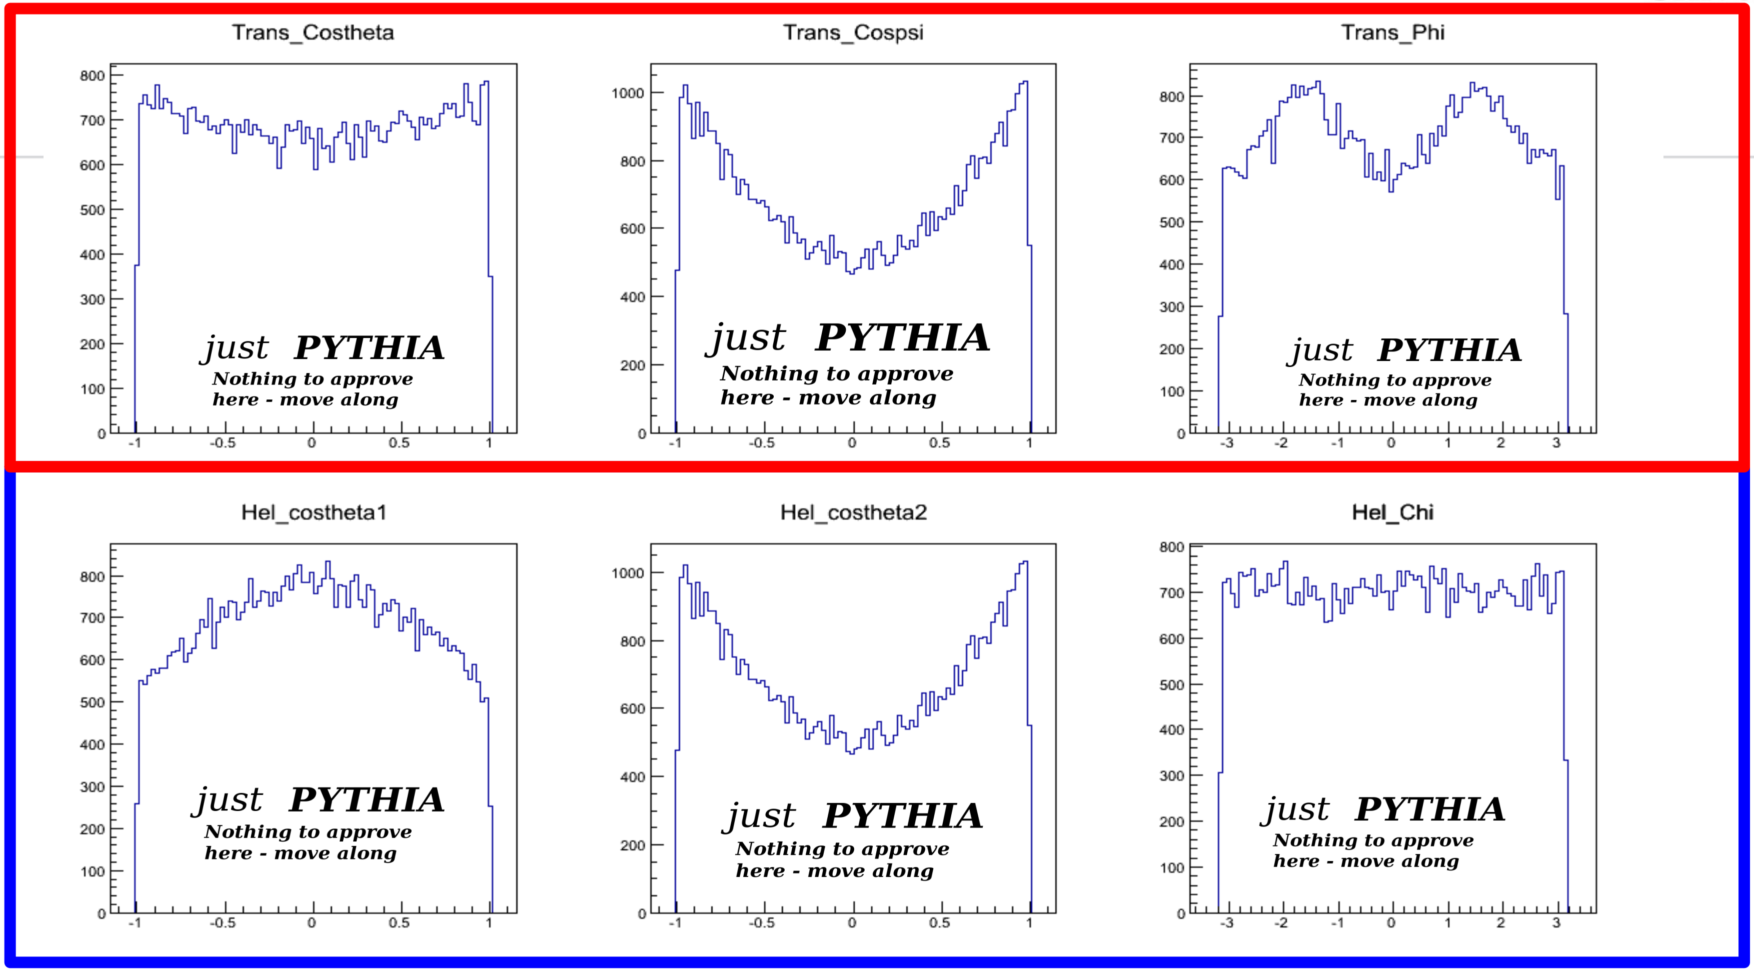
Helicity Basis



Transversity Basis



What the signal looks like

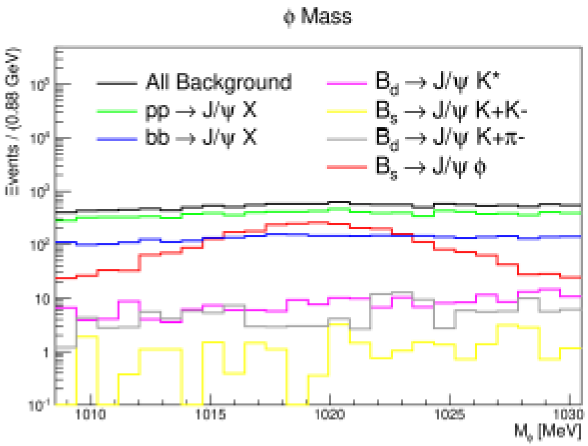


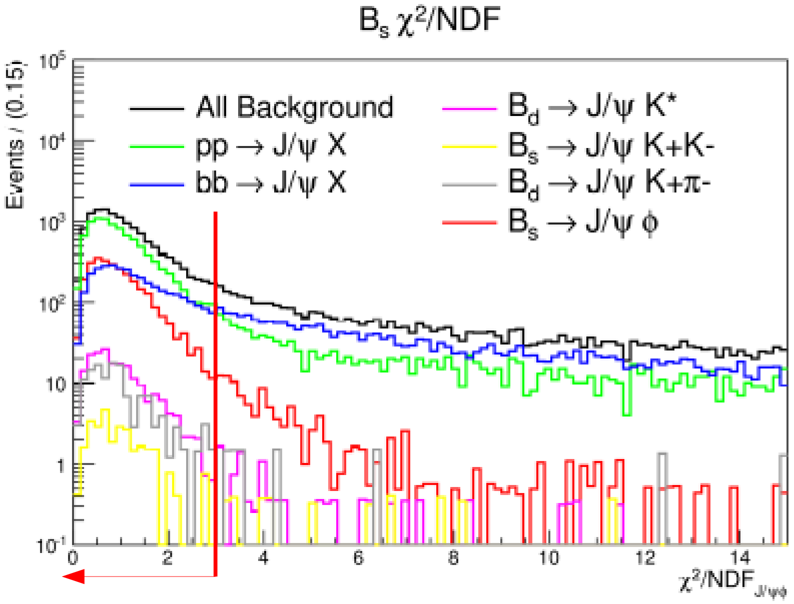
Provisional MC Generation – no cuts applied so no acceptance effects

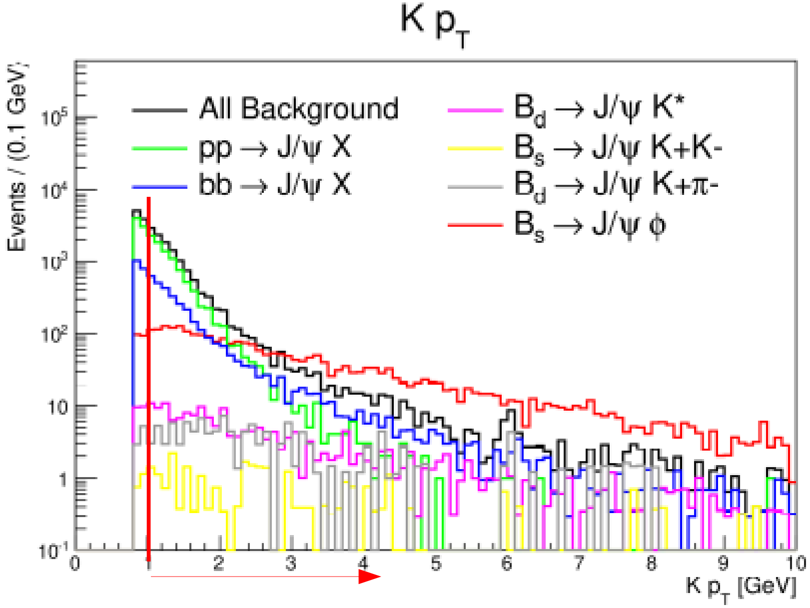
ATLAS Publications

- Time dependent untagged ϕ_s and $\Delta\Gamma_s$ from $B_s \rightarrow J/\psi\phi$ JHEP 1212 (2012) 072 – 02-AUG-12
- Time dependent flavour-tagged ϕs and $\Delta\Gamma$s from $B_s \rightarrow J/\psi\phi$ at 7 TeV Phys. Rev. D. 90, 052007 (2014) 05-JUL-14
- Time dependent flavour-tagged ϕ_s and $\Delta\Gamma_s$ from $B_s \rightarrow J/\psi\phi$ in Run 1 JHEP 08 (2016) 147 13-JAN-16
- Measurement of the CP violation phase ϕ_s in $B_s \rightarrow J/\psi\phi$ decays in ATLAS at 13 TeV 23 Mar 2019 (Conf-Note going to publication)
- Next paper will include all Run-2 data.

Deciding cuts







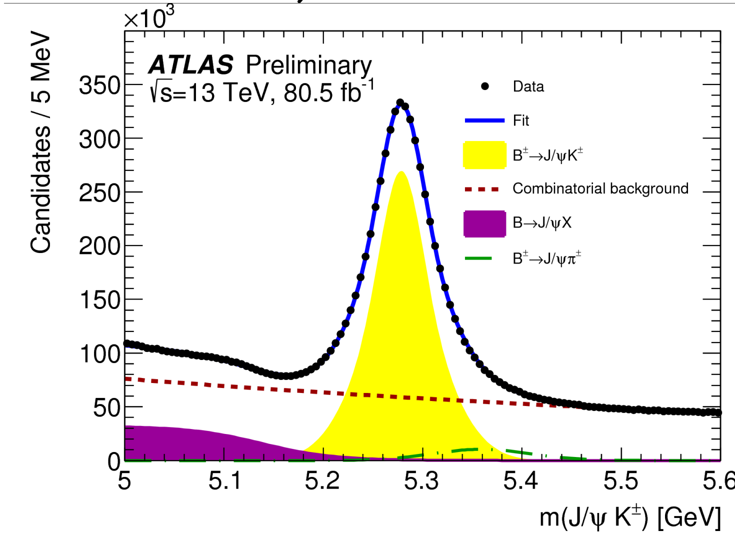
Deciding Cuts

ATLAS-CONF-2019-009

- This analysis follows are previous measurement using 19.2 fb^{-1} of $\sqrt{s}$=7 TeV and 8 TeV ("run 1")
- The new analysis uses datasets from 2015 to 2017 with $\sqrt{s}$=13 TeV totalling 80.5 fb^{-1}.
- Full decay reconstruction using inner detector and muon detectors, no K/pi separation:
  - J/ψ selection – di-muon vertex $\chi2/_{NDF}<10$, J/ψ invariant mass windows width 0.27 … 0.48 GeV (barrel → endcap)
  - ϕ selection – $p_T(K^{\pm}) > 1$ GeV, Invariant mass window 22 MeV
  - B candidates – 4-track vertex $\chi2/_{NDF}<3$, (5.15 – 5.65) GeV, no proper decay time cut.

Flavour Tagging

- The analysis gains precision with tagging information. We use opposite-side tagging (OST).
- We use 4 tagging methods: “Tight” muons, electrons, Low-p_T muons, Jet
- Charge of p_T-weighted tracks in a cone around the opposite primary object, used to build per-candidate B_s tag probability.
- Calibrated from $B^+ \rightarrow J/\psi K^+$ sample

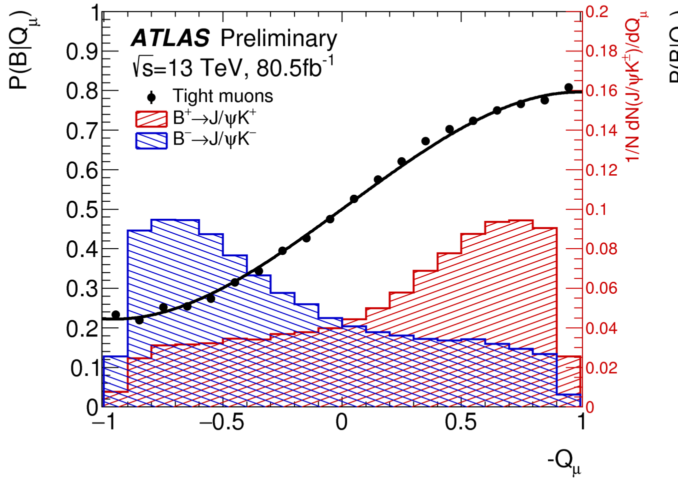


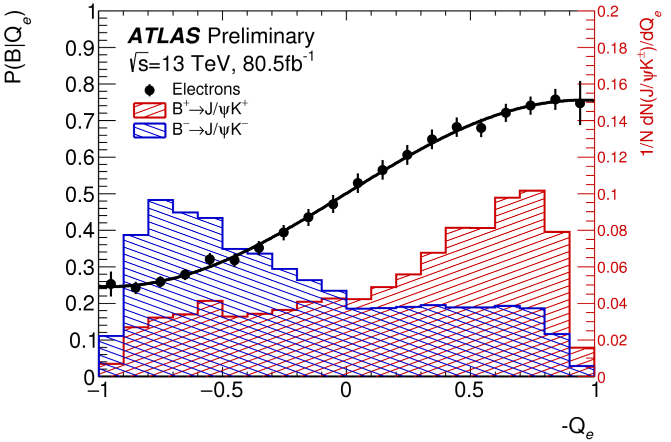
Tagging: weighted sum of charge in a cone

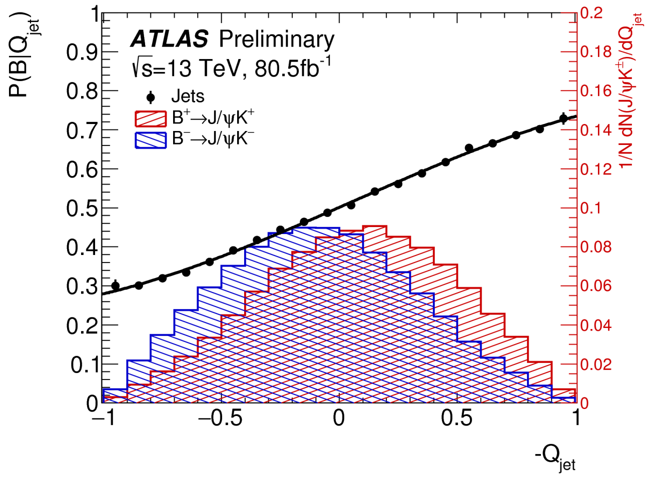
$$Q_x = \frac{\sum_i^{N \text{ tracks}} q_i \cdot (p_{\text{T}i})^\kappa}{\sum_i^{N \text{ tracks}} (p_{\text{T}i})^\kappa},$$

Tag method	Efficiency [%]	Effective Dilution [%]	Tagging Power [%]
Tight muon	4.50 ± 0.01	43.8 ± 0.2	0.862 ± 0.009
Electron	1.57 ± 0.01	41.8 ± 0.2	0.274 ± 0.004
Low-p_{T} muon	3.12 ± 0.01	29.9 ± 0.2	0.278 ± 0.006
Jet	5.54 ± 0.01	20.4 ± 0.1	0.231 ± 0.005
Total	14.74 ± 0.02	33.4 ± 0.1	1.65 ± 0.01

In events where multiple methods are available the highest dilution is selected.







Symmetries: $\{\phi_s, \Delta\Gamma_s, \delta_\perp, \delta_\parallel\} \rightarrow \{\pi - \phi_s, -\Delta\Gamma_s, \pi - \delta_\perp, 2\pi - \delta_\parallel\}$

$\cancel{\{\phi_s, \Delta\Gamma_s, \delta_\perp, \delta_\parallel, \delta_S\} \rightarrow \{-\phi_s, \Delta\Gamma_s, \pi - \delta_\perp, -\delta_\parallel, -\delta_S\}}$ (untagged fit only)

CP +1
CP -1

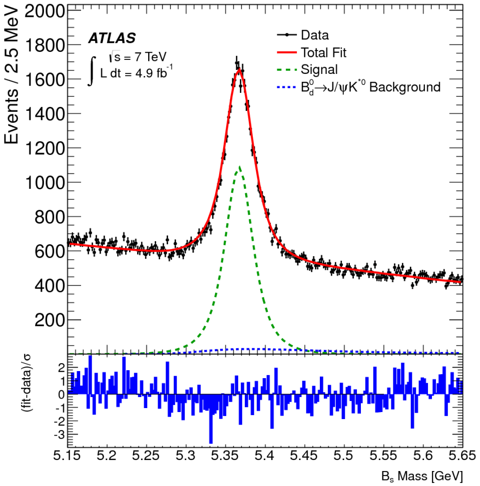
Interference terms

S-wave terms

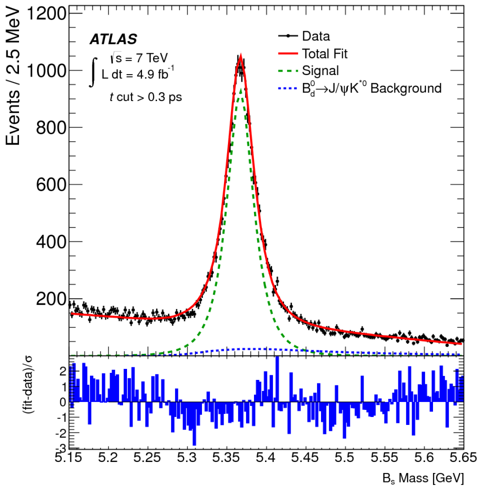
The solution with a negative $\Delta\Gamma_s$ is excluded using another LHCb measurement which determines the $\Delta\Gamma_s$ to be positive

Background description

Mass spectrum including Direct background



- To make a precision measurement it is necessary to either exclude or accurately describe the background
- The different backgrounds present are:
- Direct $pp \rightarrow J/\psi$ background
- Misreconstructed complete decays such as $B_d \rightarrow J/\psi K^*$ and $\Lambda_b \rightarrow J/\psi\ \Lambda^*(Kp)$
- Miscellaneous combinatorics from $bb \rightarrow J/\psi X$



Mass spectrum excluding direct background by lifetime cut

Unbinned Maximum Likelihood Fit

$$\ln \mathcal{L} = \sum_{i=1}^{N} \boxed{w_i} \cdot \ln(f_s \cdot \mathcal{F}_s \boxed{(m_i, t_i, \sigma_{t_i}, \Omega_i, P(B|Q), p_{T_i})}$$
$$+ f_s \cdot f_{B^0} \cdot \mathcal{F}_{B^0}(m_i, t_i, \sigma_{t_i}, \Omega_i, P(B|Q), p_{T_i})$$
$$+ f_s \cdot f_{\Lambda_b} \cdot \mathcal{F}_{\Lambda_b}(m_i, t_i, \sigma_{t_i}, \Omega_i, P(B|Q), p_{T_i})$$
$$+ (1 - f_s \cdot (1 + f_{B^0} + f_{\Lambda_b}))\boxed{\mathcal{F}_{\text{bkg}}(m_i, t_i, \sigma_{t_i}, \Omega_i, P(B|Q), p_{T_i}))\}}$$

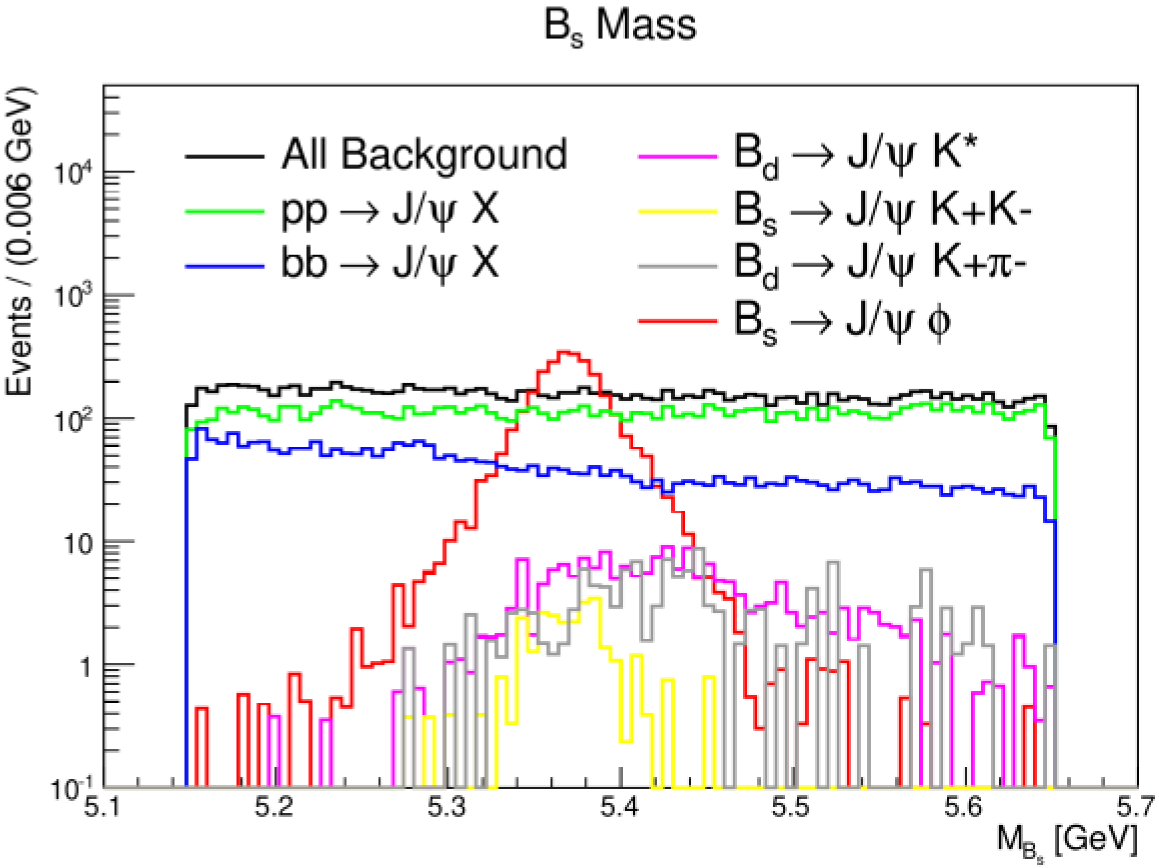
$B_d \rightarrow J/\psi K^*(K\pi)$ and $\Lambda_b \rightarrow J/\psi \Lambda^*(Kp)$ decay reflections, derived from MC, PDG and the LHCb $\Lambda_b \rightarrow J/\Lambda Kp$ measurement; fixed shape and relative contribution in the fit

Measured variables:
- B_s mass m_i
- B_s proper decay time t_i and its uncertainty σ_{ti}
- 3 angles $\Omega_i(\theta_T, \psi_T, \varphi_T)$
- B_s momentum p_T
- B_s tag probability $p_{B|Qi}$
- tagging method M_i

Combinatorial background description, derived from data sidebands; angular distribution described by spherical harmonics and fixed in the fit

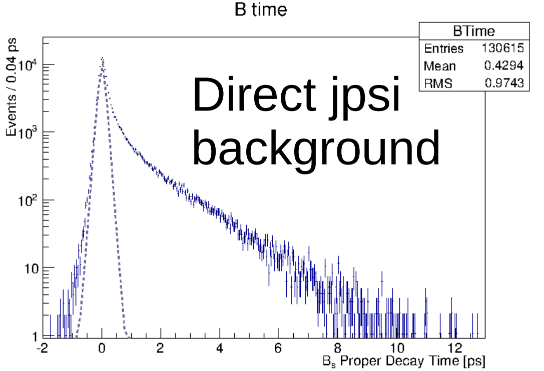
Weights accounting for **proper decay time trigger efficiency** (muons track d_0 reconstruction efficiency bias); estimated from MC

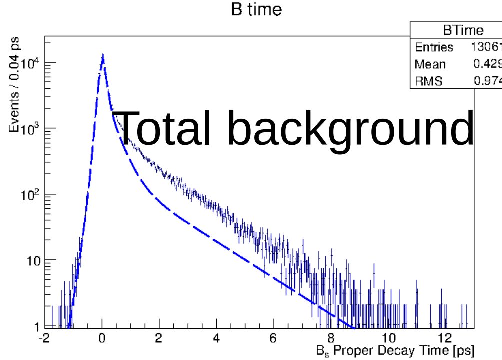
Background with Monte Carlo

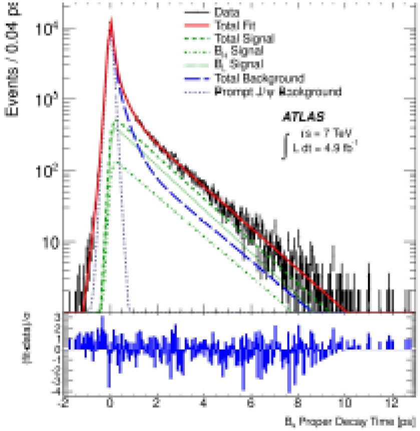


Background representation in the fit

- Time component of background:
  - Prompt background: delta function at 0, convoluted by Gauss **per-candidate resolution** σ_{ti}
  - Two exponentials representing longer-lived backgrounds
  - Small negative exponential component for events with poor vertex resolution
- Background angular shapes
  - Arise from detector and kinematic sculpting
  - Described by empirical functions with parameters determined in the fit
- Background mass model – linear function
- $B^0 \rightarrow J/\psi K^{*0}$ and $\Lambda b \rightarrow J/\psi\ \Lambda^*(Kp)$ contamination treated separately
  - fractions are determined from MC
  - mass, angular shapes - from MC
  - used in PDF but no free parameters of fit





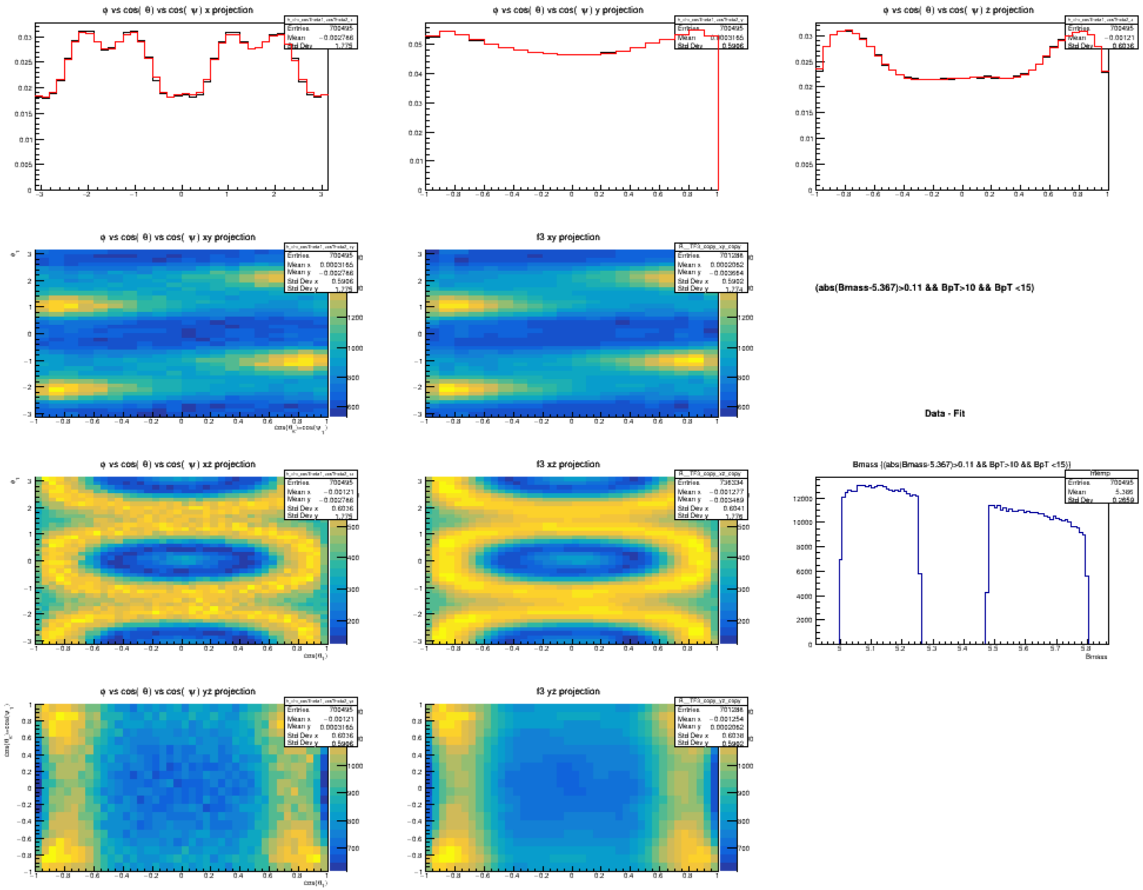


Angular Background

- The angular component of the background is shaped by detector and acceptance effects producing a non-trivial 3D shape that is also pT dependent
- The mass side bands are taken and a Legendre polynomial function is used to fit the shape. The resulting parameters are fixed and used in the main fit.
- The dedicated backgrounds are simulated with monte carlo, their shaping applied and also fit by spherical harmonics

$$
\begin{aligned}
Y_l^m(\theta_T) &= \sqrt{(2l+1)/(4\pi)}\sqrt{(l-m)!/(l+m)!}\,P_l^{|m|}(\cos\theta_T) \\
P_k(x) &= \frac{1}{2^k k!}\frac{\mathrm{d}^k}{\mathrm{d}x^k}(x^2-1)^k \\
\mathscr{P}_\mathrm{b}(\theta_T,\psi_T,\phi_T) &= \sum_{k=0}^{14}\sum_{l=0}^{14}\sum_{m=-l}^{l}\begin{cases} a_{k,l,m}\sqrt{2}Y_l^m(\theta_T)\cos(m\phi_T)P_k(\cos\psi_T) & \text{where } m>0 \\ a_{k,l,m}\sqrt{2}Y_l^{-m}(\theta_T)\sin(m\phi_T)P_k(\cos\psi_T) & \text{where } m<0 \\ a_{k,l,m}\sqrt{2}Y_l^{0}(\theta_T)P_k(\cos\psi_T) & \text{where } m=0 \end{cases}
\end{aligned}
$$

Angular Background



Kinematic Acceptance

- It is necessary to exclude (cut) low energy tracks to exclude large quantities of background.
  - The muon trigger applies at least a 4GeV cut on the muons (triggers vary according to the luminosity)
  - Kaon cuts are applied after reconstruction to reduce the background.
- This biases the angular distributions distorting the “true” distribution.
- This is attained by simulating a naïve level of physics so the angular distributions are flat, and then feeding these events through the detector simulator and applying the standard cuts.

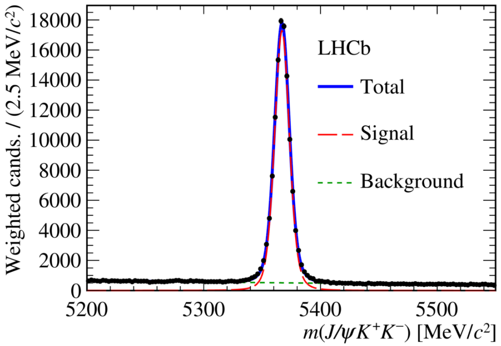
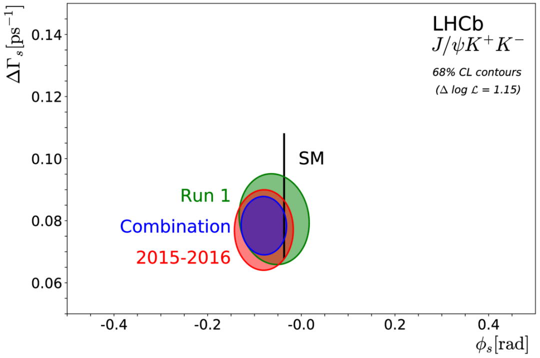
LHCb: arXiv:1903.05530
ATLAS: ATLAS-CONF-2019-009

LHCb - 2019

- LHCb have recently released an updated result.
- LHCb has particle ID hardware allowing them to significantly reduce background, but cannot record as much luminosity reducing statistics
- Resulting in a worse statistical error but better systematic error.





$\Phi_s = -0.083 \pm 0.041 \pm 0.006$ rad

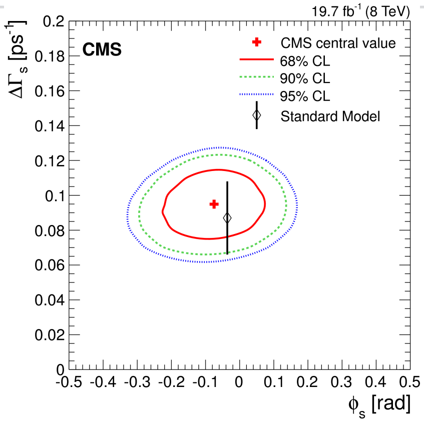
$\Delta\Gamma_s = 0.077 \pm 0.008 \pm 0.003$ ps−1

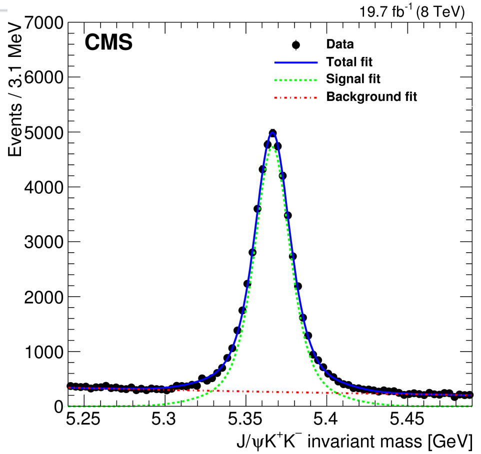
ATLAS

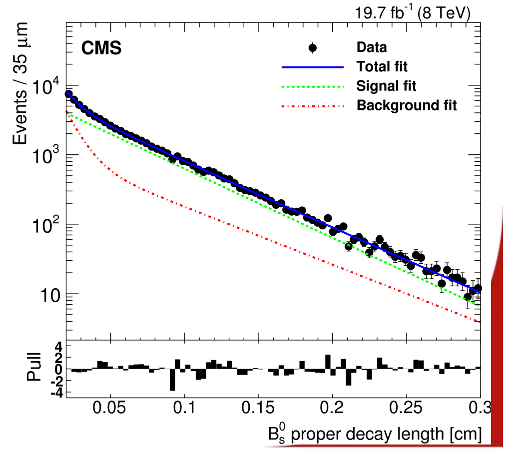
$$\phi_s = -0.076 \pm 0.034 \text{ (stat.)} \pm 0.019 \text{ (syst.) rad}$$
$$\Delta\Gamma_s = 0.068 \pm 0.004 \text{ (stat.)} \pm 0.003 \text{ (syst.) ps}^{-1}$$

CMS - 2015

- CMS have a measurement from 2015 using run-1 data.
- CMS has a similar strategy to ATLAS but cut out the direct pp background.







CMS

$$\varphi_s = -0.075 \pm 0.097\ (\text{stat}) \pm 0.031\ (\text{syst})\ \text{rad}$$

$$\Delta\Gamma_s = 0.095 \pm 0.013\ (\text{stat}) \pm 0.007\ (\text{syst})\ \text{ps}^{-1}$$

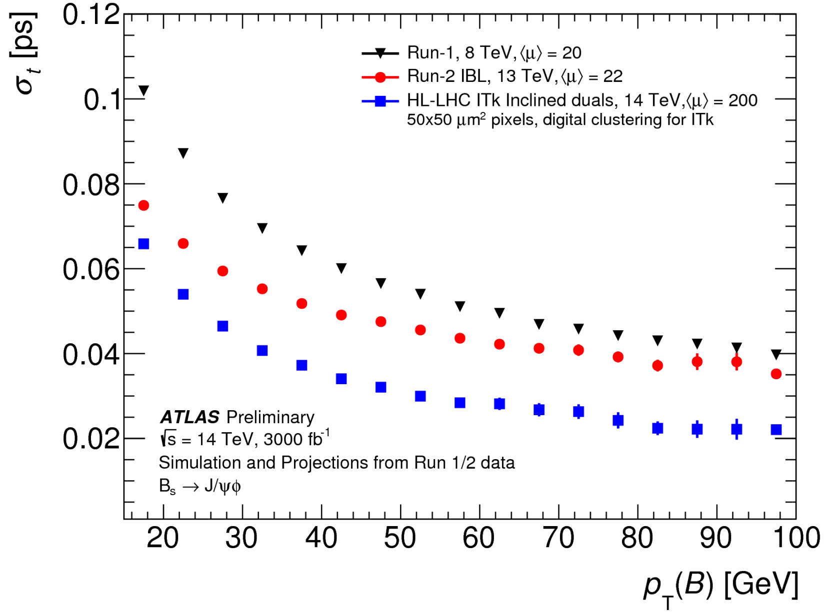
ATLAS

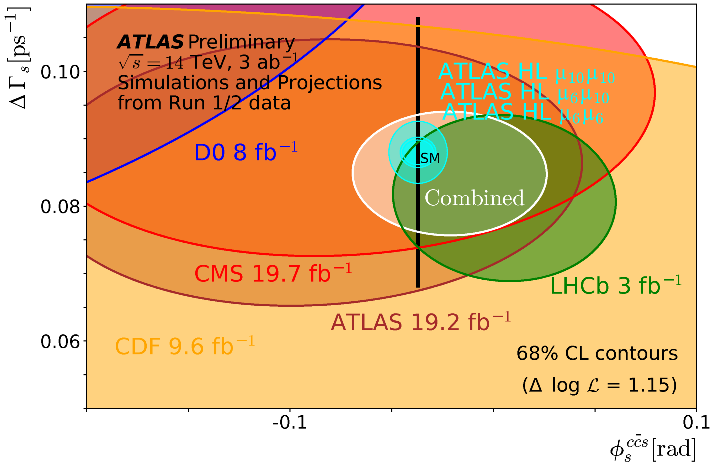
$$\phi_s = -0.076 \pm 0.034\ (\text{stat.}) \pm 0.019\ (\text{syst.})\ \text{rad}$$

$$\Delta\Gamma_s = 0.068 \pm 0.004\ (\text{stat.}) \pm 0.003\ (\text{syst.})\ \text{ps}^{-1}$$

Detector Improvements

- In run-2 IBL improves time resolution → improved ϕ_s
- We estimate ϕ_s for future analyses give various muon threshold scenarios.





Summary

- ATLAS' measurement is compatible with the standard model and other experiments.
- ATLAS remains competitive with other experiments

$$
\begin{aligned}
